RE: Progress Report for project 4N34

Enclosed is the Progress Report that you requested. Much of the sediment data is listed in the Appendix. There is a substantial amount of data that has been generated but not yet entered into the database. These data are not listed in the Appendix, but briefly summarized in the report. I see no problems meeting the June 1998 due date for the draft final report. Please contact me if you or anyone else has comments or questions.

Sincerely,

A handwritten signature in cursive script that reads "Damian Shea".

INTRODUCTION

Background

The Lower Mississippi River Ecosystem (LMRE) is a fertile delta area which is approximately 35,000 square miles in size and lies in portions of Arkansas, Mississippi, Louisiana, Tennessee, Kentucky, Missouri, and Illinois. The US Fish and Wildlife Service (Service) has established refuges in this region in an attempt to preserve and protect habitat for fish and wildlife species, including many endangered species. Over the past two decades, several studies have been conducted in the LMRE that provide compelling evidence that fish and wildlife have been exposed to high concentrations of toxic contaminants (see references in Shea 1995, 1996, and 1997a). For example, at several sites fish residues of DDT and toxaphene were greater than 10 ppm, which exceed levels considered safe for fish health and for human or wildlife consumption. It is also becoming apparent that developmental and reproductive effects (that have direct links to populations) might result at much lower residue levels (<0.01 ppm) — levels that were once considered safe and were below the analytical reporting limits of the earlier studies. At the same time, many of the refuges in this area have had little or no investigation of contaminant exposure or possible ecological effects despite their proximity to large agricultural fields, oil production platforms, and other contaminant sources. In addition, there has been very little investigation into the use, fate, residues, and possible hazards of newer pesticides commonly used on and near many of these refuges or of the potential hazards associated with other contaminants such as aromatic hydrocarbons and mercury. The Service has expressed concern about the potential impact of contaminants on fish and wildlife in this region and the lack of information and predictive tools to assess current and future hazards. Thus, the Service requested an assessment of the potential biological impacts associated with toxic contamination in the LMRE region.

In the Fall of 1994 we began Phase I of a study (under a separate investigation) to design and evaluate a conceptual approach to investigate contaminant sources, fate and associated biological effects at 26 National Wildlife Refuges (NWR) in the LMRE (Figure 1). This approach is being implemented under Phase II (which began in the fall of 1995 and is the on-going investigation) to (1) characterize the areas or ecosystems of interest (refuges and watersheds), (2) characterize contaminant sources (identify sources and estimate loadings), (3) develop contaminant fate and effects models, (4) prioritize contaminant hazards, and (5) recommend appropriate management actions. Additional details of this study were discussed by Shea (1995, 1996, 1997a).

Scientific Objectives

The FWS Region 4 Office convened a workshop in Atlanta during June 1994 to help plan an investigation of the effects of contaminants on fish and wildlife in the LMRE. The central management question motivating this study is

Do toxic contaminants pose a meaningful hazard to fish and wildlife in the Mississippi River Alluvial Valley?

Mississippi River Alluvial Plain Study Area

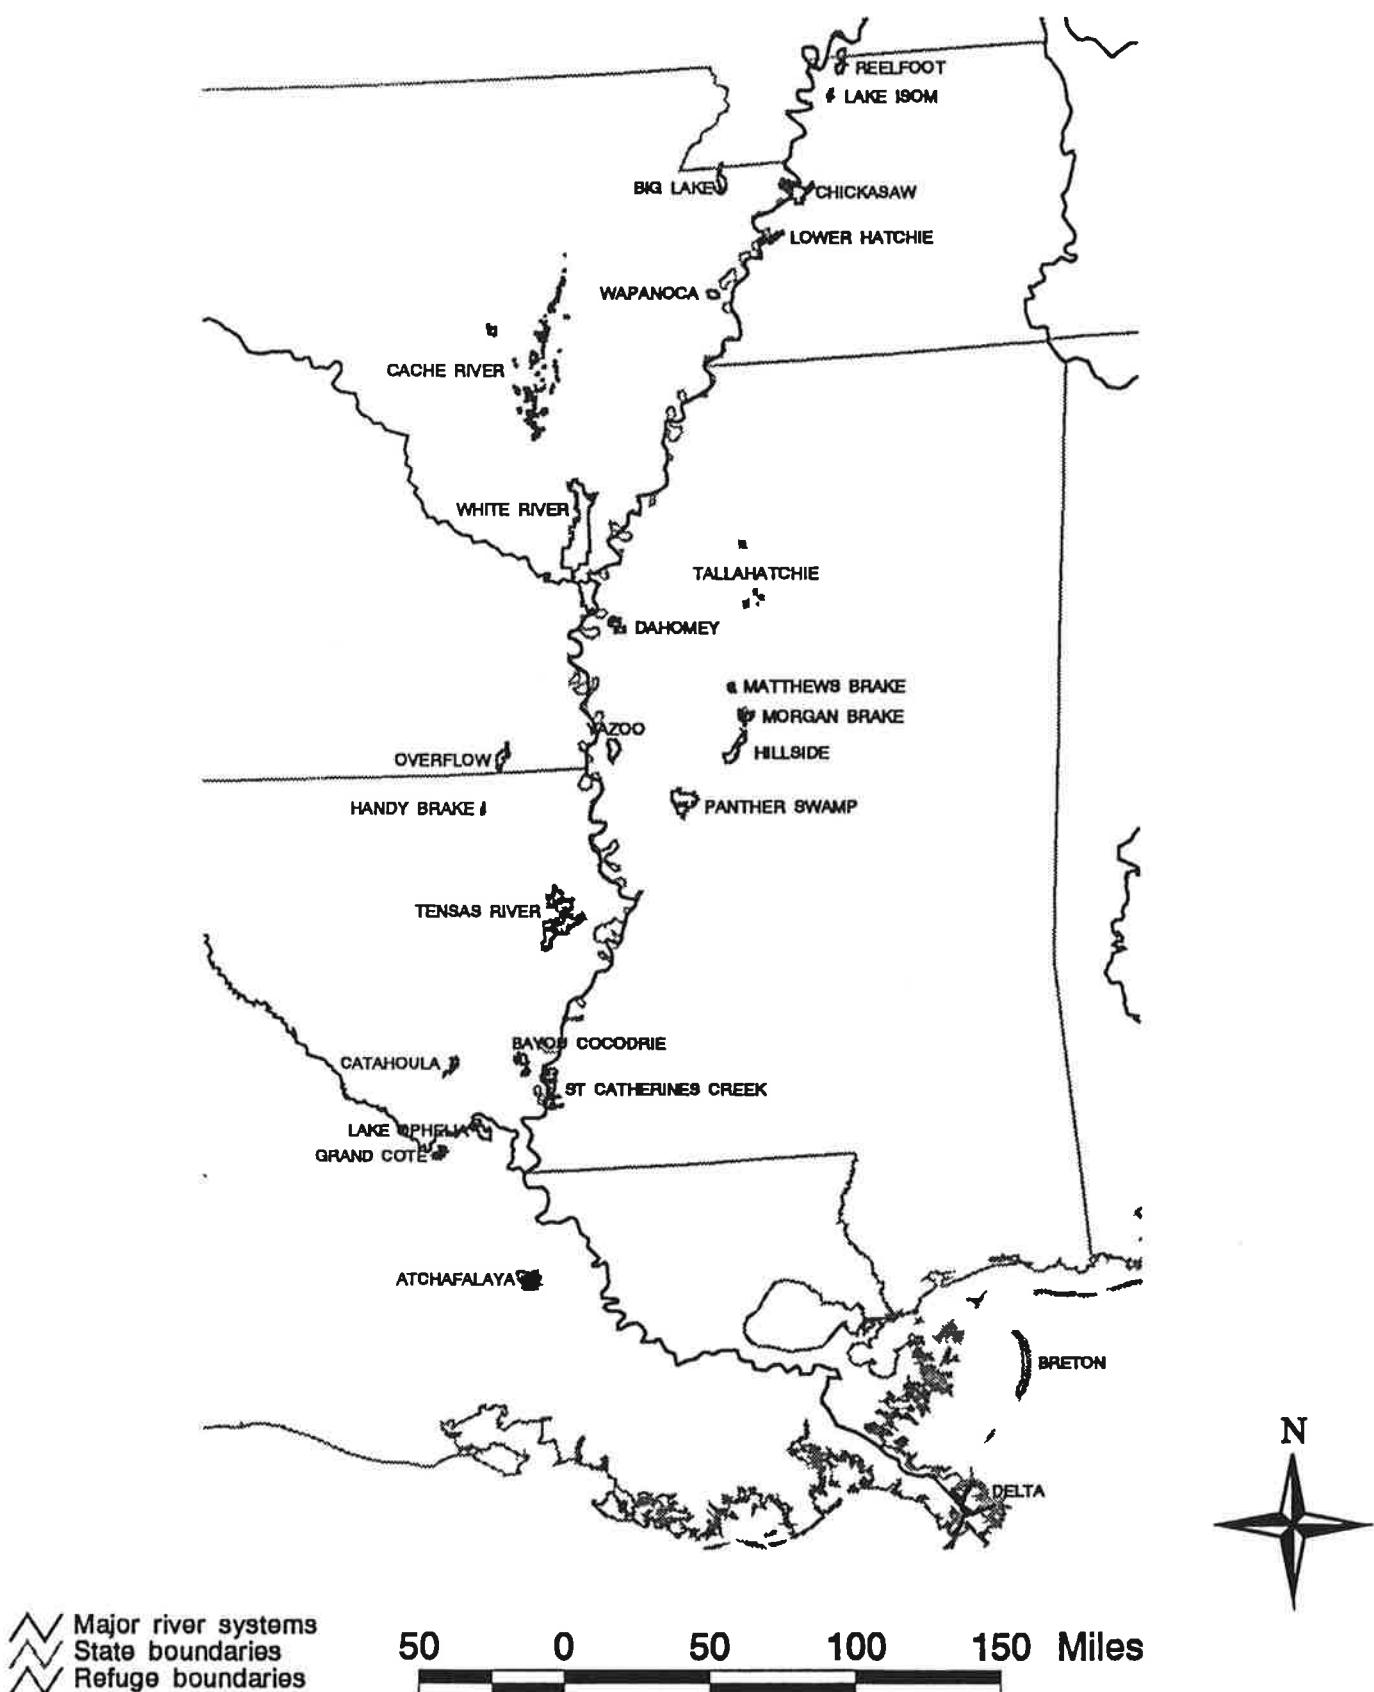

FIGURE 1

[Note that in this report, we use the term hazard to denote a condition (exposure concentration) that might result in an undesired event (death, reduced fecundity, etc.), where a hazard assessment determines the existence of a hazard, for example, by comparing predicted or measured contaminant exposure to known toxicological test endpoints (LC50s or other benchmark values). This is distinct from the often misused term of risk and risk assessment, which require estimates of probability that an undesired event will take place (Shea, 1997b). This project will identify and assess hazards; it will not provide estimates of risk.]

To provide a technical basis for answering the central management question, several scientific objectives were identified by workshop participants in two distinct categories

Contaminant Sources, Fate and Exposure

- Prioritize the contaminants of concern for each NWR and the MAV.
- Identify and quantify the dominant sources of these contaminants.
- Identify and quantify the important transport and fate processes.
- Estimate contaminant exposure (concentration and duration) in specific media.
- Estimate the spatial and temporal variability of exposure.
- Determine whether wildlife refuges act as sumps for agricultural runoff.
- Determine how various management practices (intentional flooding) affect exposure.
- Estimate the time required to decrease contaminant exposures to acceptable levels.

Contaminant Effects and Hazard

- Estimate the biological and ecological effects of this exposure.
- Estimated the hazards to specific species and to the ecosystem.
- Compare contaminant hazards to hazards from other sources of perturbation.
- Predict how hazards will change over time and how long recovery will take.
- Identify problems or hazards that require further study.
- Recommend assessment/measurement endpoints that should be monitored.

There was a workshop consensus that it will be impossible to meet each of these objectives with available resources and there was also a consensus that the project should initially focus on answering questions related to *Contaminant Sources, Fate, and Exposure* and then use this information to answer more specific questions related to *Contaminant Effects and Hazard*. Thus, the expectations have been that questions related to *Contaminant Sources, Fate, and Exposure* will be answered and an initial hazard assessment of contaminants will be completed. The specific scientific objectives have thus been refocused to include

- (1) identify and quantify sources of toxic contaminants to the 26 refuges
- (2) develop a contaminant fate model to predict order-of-magnitude exposure
- (3) measure contaminant exposure/residue in water, sediment, soil, SPMDs, and fish
- (4) develop a database/GIS of physical, chemical and biological information for the region
- (5) assess potential biological impacts and hazards using effects thresholds/benchmarks
- (6) provide the basis and design for an ecological risk assessment

Management Actions

The results and final products of this investigation are expected to provide managers with the information and tools necessary to make informed decisions about the consequences of various management options related to the hazard of contaminants to trust resources. Both the modeling and measurements we perform will provide managers with an estimate of current contaminant hazards. Comparison with previous studies, results from the sediment cores, and results from our models, together will provide an estimate of changes to relative hazard over time and following specific actions. For example: Have hazards increased or decreased over the last decade? Will hazards decrease in the future with no action? How will certain water control strategies influence hazards? How will hazards change if we stop using one herbicide and replace it with an alternative? These types of questions will be answered in our report so that management can set priorities or make decisions on various actions. In addition, a screening ecological hazard assessment will provide some perspective on the relative hazards of contaminants versus other stressors. This will not be quantitative because at present we have no means to quantify the hazards of non-contaminant stressors. However, these other stressors will be identified, linked to our ecological model (part of scientific objective number 6), and categories of relative hazards will be presented (e.g., high, medium, low, or unknown hazard levels). This could be an important tool for managers to assess the relative hazards of multiple stressors and will form the basis of (and will focus) any future ecological hazard assessment efforts.

METHODS

Modeling

We developed a contaminant fate model for each refuge using the multimedia fugacity approach of Mackay (1991). The model presently consists of a Level III *steady state* (time invariant) model that includes four environmental media or bulk compartments — air, water, sediment, and soil. These compartments are treated as assemblies of subcompartments, which can consist of air, water, solid non-living matter, and living (biotic) matter. We assume that equilibrium is attained within each compartment (e.g., between sediment and overlying water). Thus, equilibrium partitioning processes and non-equilibrium reaction kinetics are explicitly considered. Intermedia transfer processes include both diffusive-transfer processes (e.g., volatilization) and non-diffusive or "one-way" transfer processes (e.g., sediment deposition). In total, the model will consider partitioning between 10 subcompartments, four separate compartment-specific reaction (degradation) rates, 13 intermedia-transfer processes, and advection in air and water.

A Level IV *unsteady state* (time variant) model has been developed for use on refuges where sufficient information on temporal processes is available to make this type of model useful. The Level IV model is essentially the same as the Level III model, except that we allow time to vary and solve the appropriate differential equations numerically.

Data Collection and Analysis

We validate the fate model and provide direct measures of exposure by collecting water, sediment, and fish samples and deploying semi-permeable membrane devices (SPMDs) at the 26 NWRs and analyzing these samples for selected organic contaminants and metals. Samples were collected using standard field collection methods that are comparable to methods used in the BEST, NAWQA and/or EMAP programs. Fish were collected by electroshocking; sediment was collected by using a benthic grab sampler, by manual coring, and by scoop in shallow areas; SPMDs were deployed from one to three months by fixing the SPMD to submerged lines.

Water, sediment, fish, and SPMD samples have been or will be analyzed for selected organic contaminants (PAH, PCB, pesticides), metals (mostly Hg), and ancillary parameters (e.g., organic carbon in sediment). The organic contaminants are listed in Table 1. All analyses were performed using modifications to standard EPA methods. These modifications include additional sample cleanup procedures and changes to instrumental parameters that provide detection of many additional analytes (e.g., almost 50 PAH compared to EPA's 16 priority pollutant PAH) and at lower detection limits than previous studies in this region (sub ppb for most analytes in sediment, fish, and SPMDs).

Hazard Assessment

We will combine modeling and field survey results (predicted and measured exposure) with biomarker and biological effects data and published threshold values to assess the hazards that contaminants pose to trust resources. We will provide an assessment of how various management actions would affect the identified hazards to trust resources by conducting a sensitivity analysis with our model and hazard assessment. By modifying parameters that would change as a result of various management actions (water flow control, pesticide use, etc.) we will predict how these actions would affect contaminant exposure and then evaluate how this change in exposure relates to changes in biological effects or hazards to trust resources. This information will provide FWS managers with a technical basis to make decisions regarding future management actions at these NWRs.

Schedule

The project schedule has been presented in detail in Shea (1995, 1996, 1997a). Phase I of this project began in October 1994 and continued through June 1996. Phase II began in Fall 1995 and will continue through the end of 1998. A draft final report that includes all data, model results, interpretation, and recommendations is due in June 1998.

Table 1. List of organic contaminants measured in this study.

<u>Current Use Pesticdes</u>	<u>Chlorinated Pesticides and PCBs</u>	<u>Polycyclic Aromatic Hydrocarbons</u>
alachlor	alpha BHC	naphthalene
atrazine	beta BHC	2-methylnaphthalene
atrazine, desethyl-	delta BHC	1-methylnaphthalene
azimphos-methyl	gamma BHC	2,6-dimethylnaphthalene
benfluralin	heptachlor	2,3,5-trimethylnaphthalene
butylate	heptachlor epoxide	C1-naphthalenes
carbaryl	alpha chlordane	C2-naphthalenes
carbofuran	gamma chlordane	C3-naphthalenes
chlorpyrifos	trans-nonachlor	C4-naphthalenes
cyanazine	aldrin	biphenyl
dacthal	dieldrin	acenaphthylene
diazinon	alpha endosulfan	acenaphthene
diethylalanine, 2,6-	beta endosulfan	dibenzofuran
dimethoate	endosulfan sulfate	fluorene
disulfoton	endrin	1-methylfluorene
EPTC	endrin aldehyde	C1-fluorenes
ethafluralin	endrin ketone	C2-fluorenes
ethoprop	hexachlorobenzene	C3-fluorenes
fonofos	methoxychlor	dibenzothiophene
linuron	mirex	C1-dibenzothiophenes
malathion	toxaphene	C2-dibenzothiophenes
metolachlor	2,4'-DDD	C3-dibenzothiophenes
metribuzin	2,4'-DDE	phenanthrene
molinate	2,4'-DDT	anthracene
napropamide	4,4'-DDD	1-methylphenanthrene
parathion	4,4'-DDE	C1-phenanthrenes/anthracenes
parathion, methyl-	4,4'-DDT	C2-phenanthrenes/anthracenes
pebulate		C3-phenanthrenes/anthracenes
pendimethalin	PCB 8	C4-phenanthrenes/anthracenes
permethrin	PCB 18	fluoranthene
phorate	PCB 28	pyrene
prometon	PCB 44	C1-fluoranthenes/pyrenes
pronamide	PCB 52	retene
propachlor	PCB 66	benz[a]anthracene
propanil	PCB 77	chrysene
propargite	PCB 101	C1-chrysene
simazine	PCB 105	C2-chrysenes
tebuthiuron	PCB 118	C3-chrysenes
terbacil	PCB 126	C4-chrysenes
terbufos	PCB 128	benzo[b]fluoranthene
thiobencarb	PCB 138	benzo[k]fluoranthene
trallate	PCB 153	benzo[e]pyrene
trifluralin	PCB 170	benzo[a]pyrene
	PCB 180	perylene
	PCB 187	indeno[1,2,3-c,d]pyrene
	PCB 195	dibenz[a,h]anthracene
	PCB 206	benzo[g,h,i]perylene
	PCB 209	coronene

REPORT ON PROGRESS TO DATE

This section summarizes our progress on the six scientific objectives to date.

(1) Identify and quantify sources of toxic contaminants to the 26 refuges.

Work related to this objective is complete. All of the available data on important sources of contaminants to the refuges have been identified and their source loadings have been estimated and entered in the database. We have reviewed pesticide use data for the refuges and estimated off-refuge pesticide use from USDA, state and county records. All major point sources have been identified and available discharge records have been obtained. These source loads are used as input to our contaminant fate models discussed below. Note that there are no available loading data for a number of potentially important sources (e.g., oil production platforms) so uncertainties, sometimes substantial, exist in our database and model. The completed database will be provided with the final report.

(2) Develop a contaminant fate model to predict order-of-magnitude exposure.

We have completed preliminary refuge-specific, contaminant fate models based on the multimedia fugacity approach of Mackay (1991). An example output from the model is shown in Figure 2. Depending on the refuge, the model has been run for between 10 - 35 contaminants including polycyclic aromatic hydrocarbons (PAH), pesticides, and polychlorinated biphenyls (PCBs). Additional contaminants will be included in the final version of the model. All modeling software will be provided with the final report and limited training of Service staff will be available if desired.

Note that this type of model does not have the predictive capability of some other pesticide fate models (e.g., AGNPS, PRIZM), but it requires substantially less data and relies instead on more assumptions and literature values for model parameters. Use of the more predictive fate models would require data at very high temporal and spatial resolutions which would have limited the study to a single refuge. Our contaminant fate model also is useful for any organic contaminant, including PAHs which are potentially very important in the refuges with oil production. At the very least, our model provides an evaluative characterization of contaminant fate at each refuge and throughout the LMER – comparisons can be made amongst refuges and hypothesis (related to various management actions such as changes in pesticide use or water flow) can be tested. At best, the model provides an order-of-magnitude prediction of actual contaminant exposure that results from reported use and discharge.

(3) Measure contaminant exposure/residue in water, sediment, soil, SPMDS, and fish.

This is the most critical objective of the study. It provides the basis for assessing hazards, comparison amongst refuges and with reference sites and historical data, and is used for validating our model. All of the field sampling has been completed. We have collected abiotic samples (water, sediment, and soil), deployed SPMDS, and measured environmental quality parameters (temperature, DO, etc) at all 26 refuges. In addition, fish (and sometimes shellfish) were collected at Atchafalaya, Catahoula, Delta, Chickasaw, Panther Swamp, Reelfoot, Big

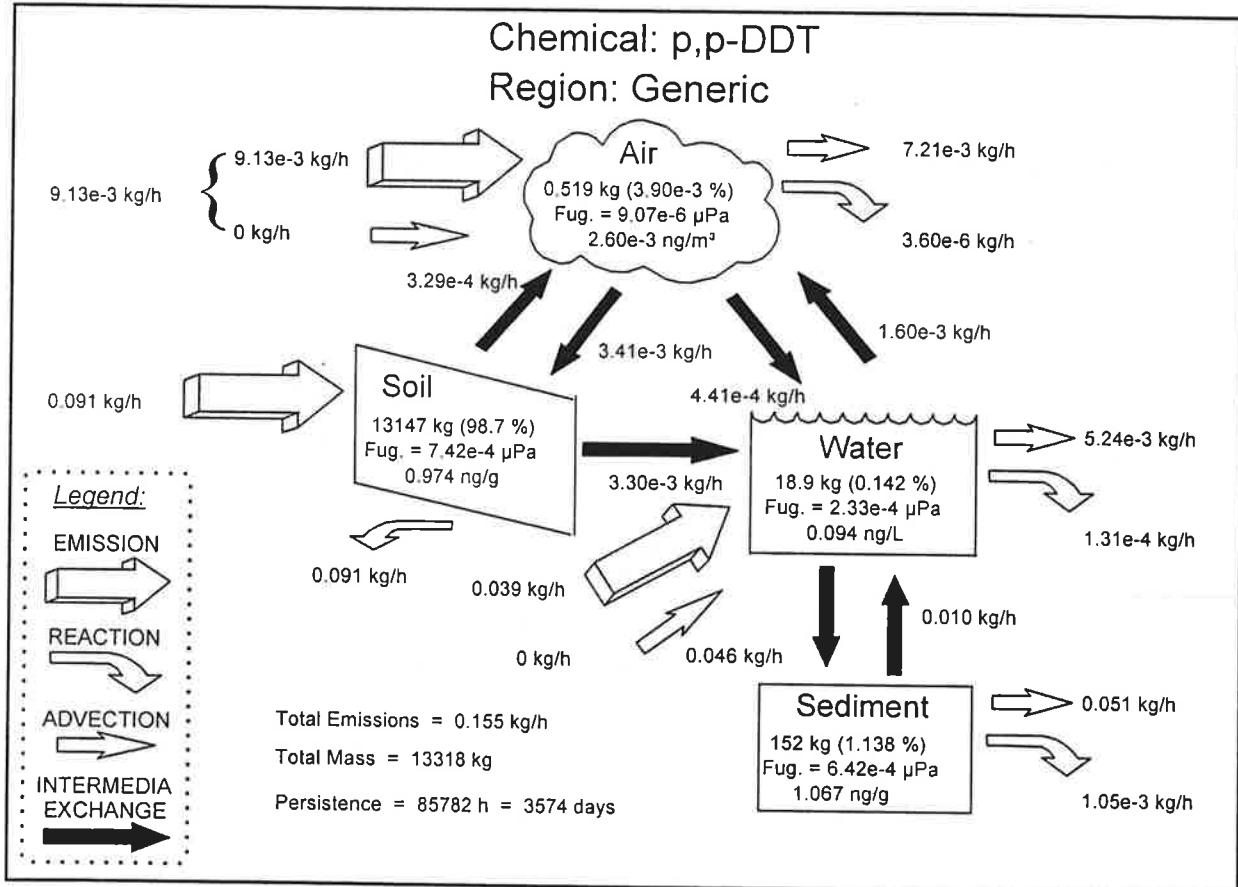

Figure 2. An example of the graphical output from the steady-state contaminant fate model.

(5) Assess potential biological impacts using effects thresholds/benchmarks.

Threshold and benchmark levels for biological effects have been reviewed and summarized. In the final report, thresholds will be compared to measured and predicted exposure concentrations to assess potential hazards.

(6) Provide the basis and design for an ecological risk assessment.

The ultimate goal of this project is to place some perspective on the potential biological impacts resulting from contaminant exposure and the importance of this exposure relative to other stressors (e.g., habitat alteration). This will help the Service to identify and prioritize management actions and will help in the design of refuge-specific and regional ecological risk assessments. We have completed qualitative ecological models of stressor-response relationships for each refuge (see Figure 3 for example). These models and analyses will be combined with the contaminant exposure/effects information to provide the basis for an ecological risk assessment.

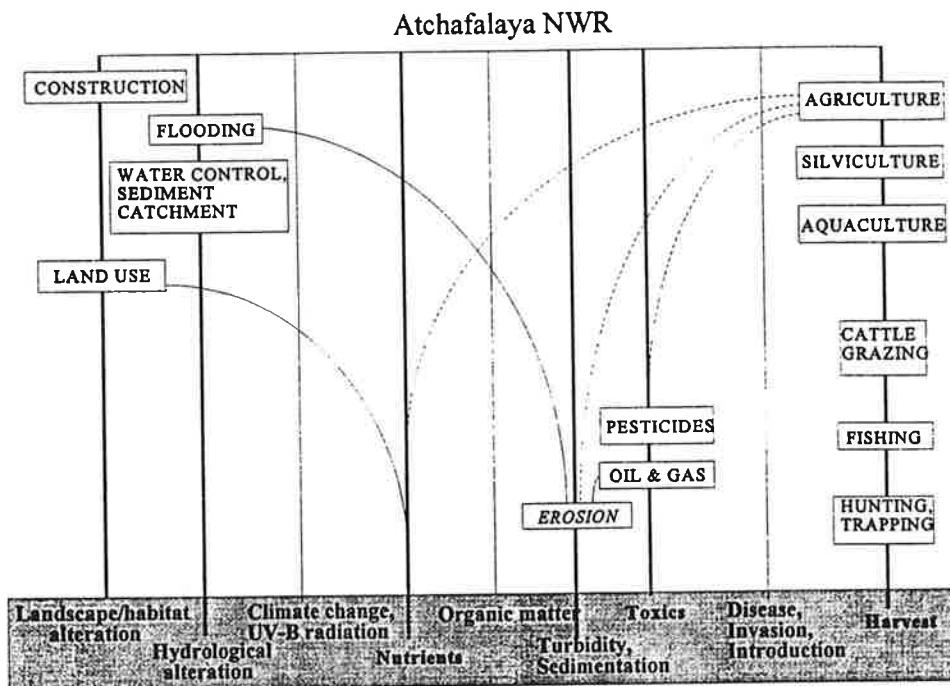

Fig. 3: A simplified conceptual model showing activities and potential stressors within the Atchafalaya NWR, which has been called the "greatest river swamp in the U.S." Only known activities and potentially significant or known stressors are highlighted; interactions across activities and stressors are conjectural. Further definition of certain activities is provided below. The agricultural influence on activity-stressor interactions relates to pre-1995 activities.

Construction

Road & trail maintenance (gravel), campsites (WMA), shooting ranges (WMA), dump & burn pile within fenced equipment area (WMA), privately-owned cabins within inholdings, WMA headquarters & equipment shed, ATV trails, water-control structures (including sediment catchments).

Land use

Ducks Unlimited waterfowl impoundment (under construction), >1 square mile moist-soil unit/waterfowl impoundment area (planted with soybeans in the summer), food plots for foraging (planted with brown millet & cow pea), reforestation and green-tree reservoir.

Flooding

Gates allow Mississippi floodwaters to pass through refuge; last opened in 1973.

Oil & Gas

Active & inactive oil wells and exploration (e.g., Happytown Oil & Gas Field, Nasser Oil & Gas Company, Gap Energy, Inc.), historic fuel refinery (WMA).

Harvesting pressures

Historic 260-acre cropland (pesticide application prior to 1995; on-refuge farming ceased in 1995; 60 acres currently left fallow, 200 acres have been reforested), crawfish farming (southeast corner of refuge), cattle grazing (east protection levee), timber sales, alligator trapping (30 alligators per year), recreational fishing (boat and bank), commercial fishing (e.g., ~22 million lbs. crawfish per year taken from basin, including catfish, buffalo & drum), hunting (e.g., white-tailed deer, fox & gray squirrels, wild turkey).

* WMA = located on Sherburne Wildlife Management Area land

APPENDIX

SEDIMENT SAMPLING SITES AND SOME PRELIMINARY DATA

Table AT-1. Sediment sample collection sites at Atchafalya NWR, LA.

Site ID	Site Location
AT01	Bayou Close
AT02	Bayou Stiff
AT03	Alabama Bayou
AT04	Johnson Bayou
AT05	Little Alabama Bayou
AT06	Swamp on east side of refuge - north end
AT07	Swamp on east side of refuge - south end
AT08	Active & inactive oil sites - tank battery area ~ 1.5 miles east of Big Alabama Bayou
AT09	Waterfowl impoundments - north unit
AT10	Historic oil containment site
AT11	Historic fuel refinery
AT12	Active & inactive oil sites - tank battery area south of Happytown Road 50 meters east of Refuge Road
AT13	Active & inactive oil sites: capped well off Happtown Road ~ 150 meters west of Alabama Bayou
AT14	Active & inactive oil sites: well site off Hwy 975, ~.3 miles south of Refuge HQ

Table CR-1. Sediment sample collection sites at Cache River NWR, AR.

Site ID	Site Location
CR01	Cache River north of Amagon
CR02	Cache River north of Hwy 33 to south of Hwy 17
CR03	Cache River 2 miles downstream and 2 miles upstream of Cache Bayou
CR04	Cache River ~ 5 miles north of White River confluence
CR05	Black Swamp - State Access Area south of Gregory; north of HQ near boat launch
CR06	Cache Bayou
CR07	Gum Flat Slough
CR08	Bayou Deview
CR09	Locust & Cypress Creek Ditches
CR10	Overcup Ditch
CR11	Roaring Slough
CR12	Culotches Bay
CR13	Creek draining landfill north of Amagon
CR14	Black Swamp - State Access Area at Gregory 200M east and 50M south of Ramp
CR15	Black Swamp - east of Crutcher Cemetery ~70 M north of southern WMA boundary, NW of Dupree Lake
CR16	Black Swamp - east of Cache River, south end road heading west at Vivelle, ~ 75M west from end of field road
