## ALASKA - YUKON

# WATERFOWL BREEDING POPULATION SURVEY

May 16 to June 13, 1998

Ву

Bruce Conant Deborah J. Groves

U.S. Fish and Wildlife Service Juneau, Alaska

TITLE: Waterfowl Breeding Population Survey:

Alaska-Yukon (Crew Area 1)

STRATA COVERED: 01, 02, 03, 04, 05,06, 07, 08,

09, 10, 11, 12

**DATES:** May 16 to June 13, 1998

DATA SUPPLIED BY: Bruce Conant and Deborah J. Groves

U.S. Fish and Wildlife Service, Juneau, Alaska

#### **ABSTRACT**

Alaska-Yukon was again blessed with a generally widespread, early spring break-up in the interior and on the North Slope with perhaps a more normal spring phenology on the western tundra. Overall, there was little flooding and habitat conditions should be basically favorable for waterfowl production throughout most of the Alaska-Yukon waterfowl nesting habitat.

Generally, duck populations increased in size from 1997. Changes in duck populations by category are as follows. Dabblers are up 41% from last year, are 56% above the 10-year average, and are 117% above the long-term mean. Divers are up 23% from 1997, up 3% from the 10-year average, and are up 10% from the long-term mean. Miscellaneous are up 39% from 1997, down 2% from the 10-year average, but are down 16% from the long-term mean. Total ducks are up 37% from 1997, up 36% from the 10-year average, and are 59% above the long-term mean.

Overall, goose production should be above average in the interior but only average on the western tundra.

Trumpeter swan production should be above average throughout most of Alaska. Tundra swan production should be perhaps only average on the western tundra and above average on the North Slope.

#### INTRODUCTION

This year Migratory Bird Management - Juneau completed the 42nd consistent, standardized waterfowl breeding population survey in Alaska. This data set continues to increase in value as a basis for continental, flyway, and state-wide management of the waterfowl resource. The continuation of this historic survey is highly recommended.

We are indebted to, Joe Wulfkuhle, Bill Filkins, Tim McMenamy, Mark Patrick and others at OAS for providing vital maintenance for the aircraft. Glenn Elison, Russ Oates, John Sarvis and others in the regional office provided needed support. Special thanks to Rod King, Mike Rearden, Daryle Lons, Tom Early, Sally Jo Collins and Leslie Kerr for providing housing and/or vehicles or other logistical support. We enjoyed and benefited much from visiting with refuge personnel and others, especially in the bush. We again used a custom computer program created by Jack Hodges for data entry and analyses. We recorded habitat conditions in Alaska-Yukon with our hand held video camera during the survey and also provided an interview in the foothills of the Brooks Range for inclusion in the annual waterfowl status audio visual production by MBMO for the continent.

#### **METHODS**

Survey methods follow "Standard Operating Procedures for Aerial Waterfowl Breeding Ground Population and Habitat Surveys in North America", as revised in 1987. Pond data presented in Table 9 are three year averages from past pond counts using standard methods.

For the sixth year a Global Positioning System (GPS) unit in the aircraft was used for precise navigation along transect lines. The installation of a second GPS unit married to a large scale Course Deviation Indicator (CDI) on the pilot's side of the instrument panel further eases the piloting duties and enhances the repeatability of flying segments which have poor landmarks. The combination of GPS navigation, experimental satellite transmission of data to ground based computers, and recent advances in voice recognition technology offer enticing possibilities for the future. Perhaps someday voice observations attached to precise locations from anywhere over the earth can be sent directly from survey aircraft instantaneously to computers anywhere on the planet. At such a time, one could watch the results of the North American Waterfowl Population Survey accumulate before one's eyes at a computer screen at command central at Laurel, Maryland.

Data entry into note book computers, in the field, has now become the standard operating procedure for continental aerial waterfowl surveys. All stratum summaries and tables for this report were again computer generated. Data were provided to the Office of Migratory Bird Management (MBMO) via electronic mail from Juneau after completion of the survey.

The survey design contains 12 strata with 232 segments. The Copper River Delta (stratum 07) was surveyed again this year and the results included in place of the average figures used in past years. The Alaska unit contains 214 segments each 16 miles in length and 10 segments each 8 miles in length. The Yukon unit has 8 segments each 18 miles in length. All segments were flown again in 1998.

The unique turbine Beaver (N-754) was again used for the survey making its twenty second consecutive trip around the course in about 100 hours of flight time. As always, it made completion of the survey both safe and efficient. This unique aircraft has provided the platform from which observations were made for over half the history of the survey. It continues to be recognized as an Alaskan harbinger of spring.

A six year (1986-1991) helicopter-fixed wing comparison study in Alaska resulted in the development of new visibility correction factors (VCFs). New average rates specific for waterfowl habitats in Alaska; boreal forest (strata 1-7), tundra (strata 8-11) and the Old Crow Flats in Canada (stratum 12) were employed starting in 1992 and also were applied to the historical data set.

Because of a slight difference in the application of the VCFs for a few specific years (1986-1991), the data presented here are slightly different for some species for those years than those presented by MBMO. Both interpretations reflect a major step in the direction of presenting a more accurate picture of continental duck populations for the last half of this century. Also, in our analyses we do not apply any VCF to Canada Goose observations nor do we double single observations for Canada and White-Fronted Geese or Swans as MBMO does.

We now have a publication out which analyzes the history of loon observations during this survey and also from the North Slope. Tables 5,6 and 7 have been added to this report which detail ten year trends in red-throated, Pacific and common loons for only our survey areas respectively.

## WEATHER AND HABITAT CONDITIONS

This year in Alaska we had delusions of a super early spring break-up, prompted by the widespread, warm temperatures experienced in late March. A cool April dashed our dream and the result was, as Brina Kessel says, a "normal early" spring throughout most of the interior. A dry summer and fall last year coupled with below average snowfall made parts of the interior extremely dry this spring. On the western tundra the cool weather coupled with lots of precipitation continued in May and June resulting in perhaps a "normal" spring phenology there. The North Slope of Alaska is reported to be opening up early and the Old Crow Flats in the Yukon was completely thawed out and very green during the survey. Only minimal flooding from spring break-up was noted throughout the survey areas, although the western tundra was definitely on the wet side. We experienced some windy weather during parts of the survey which could have affected waterfowl observableness to an unknown degree.

## BREEDING POPULATION ESTIMATES

A. <u>Ducks</u>: Changes in selected species and groups are as follows with all species presented in Table 2 (numbers in thousands).

	1998		Percent	Change From
Species	Indices	1997	10-year mean¹	long-term mean <sup>2</sup>
Mallard	836.1	+ 43	+ 96	+189
Wigeon	1196.9	+ 26	+ 80	+181
G.W. Teal	678.9	+ 33	+ 35	+137
Shoveler	852.5	+ 71	+ 102	+338
Pintail	946.0	+ 46	+ 8	+ 8
Total Dabblers	4510.7	+ 41	+ 56	+117
Canvasback	105.4	+135	- 5	+ 25
Scaups	927.9	+ 16	<b>-</b> 0	+ 3
Bufflehead	46.7	+ 16	+ 16	+ 8
Total Divers	1217.7	+ 23	+ 3	+ 10
Oldsquaw	90.9	+ 33	- 8	- 38
Eiders	13.5	+ 2	+ 33	- 55
Scoters	348.4	+ 48	- 2	<b>-</b> 9
Total Miscellaneous	477.4	+ 39	- 2	- 16
TOTAL DUCKS	6205.8	+ 37	+ 36	+ 59

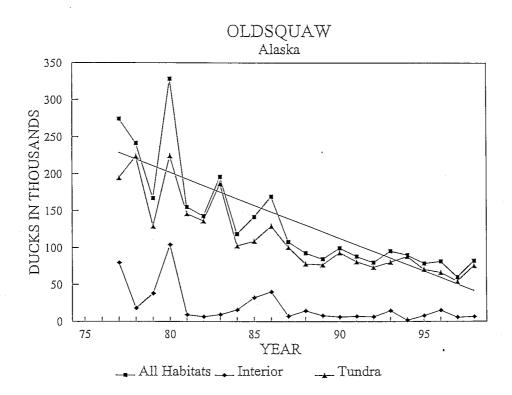

<sup>&</sup>lt;sup>1</sup> Average for Alaska-Yukon (strata 1-12) for 1988-1997.

<sup>&</sup>lt;sup>2</sup> Average for Alaska-Yukon (strata 1-12) for 1957-1997.

Total dabblers increased dramatically from 1997 and are above both the 10-year average and the long-term mean. Many flocked dabblers were noted this year, usually a sign of displaced prairie nesters. Mallard, wigeon, shoveler, greenwinged teal, and pintail numbers all increased substantially from last year. In Alaska all populations of dabbler species are well above both averages, except for pintails which are only slightly above both averages.

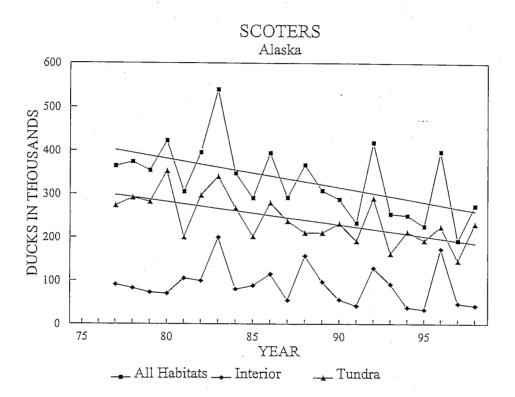

Canvasback populations increased sharply from last year and are slightly below the 10 year average but above the long term mean. Scaup numbers increased significantly from 1997, both in the interior and on the tundra. Bufflehead numbers increased from last year and are above both averages.

Oldsquaw numbers increased from last year but remain significantly below the long term mean. The steady downward slide needs to be investigated. Here is a graphic presentation of the last 22 year trend in the oldsquaw index.

Based on a small sample, the eider index shows a slight increase from last year but remains well below the long term average.

Total scoter numbers increased substantially from last year but are below long term averages. The tundra scoters and those on the Old Crow Flats accounted for all of the increase. Interior scoter numbers decreased slightly from last year. While not as dramatic of a decrease as oldsquaw, the last 22 year graph of the scoter index is alarming.

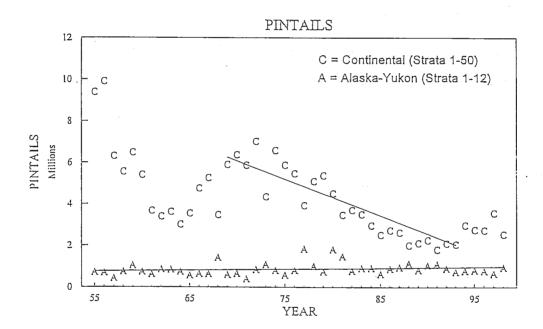

Total duck populations increased from last year and are well above both the 10-year average and the long-term mean.

Historical data from this survey, 1957-1994, have been analyzed and a major paper detailing the results has been published. Two lines were fitted to the duck data because of the increased visibility from the use of the turbine beaver (N-754) beginning in 1977. Because of the need to partition all of the historical duck data into two parts (1957-1976/1977-present), the comparisons to just long-term averages presented above may be misleading.

The generally early arrival of spring in the interior will enhance production. A more normal spring break-up on the western tundra should result in only average production there. Overall, an above average rate of duck production can be expected this year from a major portion of Alaska and the northern Yukon Territory. The results of similar surveys on the North Slope of Alaska will be reported separately.

Intensive waterfowl breeding population surveys have been conducted over all the major tundra habitat in Alaska during the last 10 years. A detailed comparison of the results of these expanded surveys over the years with this historical survey is underway for all of our tundra strata. The comprehensive duck production surveys conducted in recent years in Alaska remain on hold. A detailed analysis and summary report of those surveys are in progress.

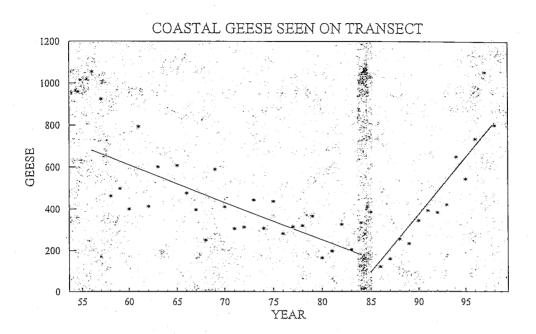

The pintail has been Alaska's most numerous nesting dabbler (recently surpassed by wigeon) and in recent years a significant proportion of Pacific Flyway pintails have been raised in Alaska. The following graph depicts pintail populations measured in Alaska-Yukon (minus the North Slope) in relation to continental (strata 1-50) populations since 1955. Fitted lines show a dramatic decline in continental populations since 1969 (p < .01) and a slight increase in Alaska populations (p = .07) over the history of the survey. This year Alaska hosted 38% of the continental index. The recent, slight increase in the continental pintail index is encouraging.

This survey was designed for ducks but other species (geese, swans, cranes, loons) are recorded routinely and an impression of their welfare is developed from our observations and the reports of others in the field.

B. Geese: The following graph depicts the trend of all geese recorded on the 5 segments of the duck survey within the coastal zone of the Yukon-Kuskokwim Delta (actual geese seen on transect only). One year, 1964, was excluded because of the extreme weather conditions experienced that year (King and Conant 1983). Two lines were fit to these data (first 1957-1984, second 1985-1998). Restricted hunting regulations were first employed in 1984 and in subsequent years within the Yukon-Kuskokwim Delta Goose Management Plan. Thus data for 1985 and the years following probably reflect a response of goose populations (mostly

white-fronts and cacklers) to those restrictions. The recent, dramatic upward trend is heartening and continued surveys in the years ahead will reveal whether populations can be maintained or even increased from former levels as hunting effort increases.

Probably only an average rate of goose production can be expected this year on the western tundra.

A progress report by Migratory Birds - Anchorage on the thirteenth year of an intensive aerial survey program on the coastal goose nesting zone of the Yukon-Kuskokwim Delta will be forthcoming.

The specialized survey for Dusky Canada geese that this project had flown for 8 continuous years (1983-1990) was discontinued in 1991. The more extensive survey flown on the Copper River Delta by Migratory Birds - Anchorage since 1986 is now the breeding population survey which best monitors this nesting population. The results of that effort will be detailed elsewhere.

Little specific information on other populations of white-fronted and lesser Canada geese is available, but production should, on the whole, be above average for interior Alaska.

#### C. Swans:

1. Trumpeter - A census of trumpeters, after hatching, on the breeding grounds in Alaska in 1995 found 15,823 total swans. Swan observations from boreal forest strata (1-4, 6 and 7) on the duck survey in 1998 suggest a population of 13,700 adults and subadults. In Alaska, production this year should generally be above average. Another complete census of trumpeters in Alaska is planned for the year 2000.

2. Tundra - The population index from the tundra strata (8-11), not including the North Slope, is 156,900; an increase of 1% from last year and 25% above the 10-year average. The breeding index (singles and pairs) is 83,200; up 1% from 1997 and 27% above average. Overall, average production is expected from tundra swans for Alaska in 1998.

## D. Cranes:

The Sandhill Crane index was 48,600 for Alaska, unchanged from 1997 but 3% above the 10-year average.

#### E. Loons:

- 1. The Red-Throated Loon index for Alaska was 7,900, down 16% from 1997 and 16% below the 10-year average.
- 2. The Pacific Loon index for Alaska was 51,700, up 57% from 1997 and 16% above the 10-year average.
- 3. The Common Loon index for Alaska was 8,300, up 28% from 1997 and 8% above the 10-year average.

#### CONCLUSION

Increased populations of total ducks were found in these northwestern strata in 1998. Some populations of geese and trumpeter swans were increased in size from last year. Sandhill crane and tundra swan populations remained stable.

The basically widespread, early arrival of spring in the interior and the mainly normal conditions on the western tundra should favorably affect waterfowl nesting and production in most Alaska-Yukon strata again in 1998. Extremely dry conditions in parts of the interior and the wet, cool spring on the west coast of Alaska may have a depressing effect. Overall, duck, goose and swan production should be generally above average in the interior and average on the western tundra.

A big unknown is how well the many flocked dabblers recorded throughout the survey will reproduce, especially if most of them are displaced prairie nesters.

In contrast to a basically optimistic outlook, a note of caution needs special emphasis for the declining populations of sea ducks (especially eiders, oldsquaw and scoters) and also red-throated loons.

#### FOOTNOTES

A Telonics, telemetry, receiver-scanner is an integral component of the special survey aircraft used. Extensive coverage of most waterfowl nesting habitats in Alaska (except the North Slope) was accomplished. We did not have any radio frequencies to monitor this year.

Two swan nests noticed on transect on the Old Crow Flats in the Yukon exhibited the typical moat around them from nest construction, a characteristic of Trumpeter Swans.

There has been a significant invasion of ringneck ducks into Alaska over recent years (1984-1998).
