INTRODUCTION

Trans-Alaska pipeline investigations, begun in 1970, have collected data on migration, breeding distribution and habitat requirements of birds on the Beaufort Sea, Arctic Coastal Plain, Prince William Sound and other areas that would be influenced by the pipeline.

Storkersen Point ($70^{\circ}25'N$, $148^{\circ}15'W$) lies on the Arctic Coastal Plain 20 km northwest of the producing oil fields of Prudhoe Bay. The 18 km^2 Storkersen Point study area has been the site of a seven year investigation with three major objectives: 1) develop a wetland classification system; 2) determine the importance of the coastal plain to waterbirds and 3) determine the abundance of aquatic macroinvertebrates in tundra ponds, and identify use of invertebrates by waterbirds in order to evaluate the impact of oil spills and petroleum development on waterbirds (Bergman et al. 1977; Howard 1974; Abraham 1975; Derksen et al. 1976; Heinz and Koob 1977). Specific objectives of the 1978 field season at Storkersen Point were: 1) determine breeding populations of birds by weekly ground censuses on established transects; 2) monitor waterbird use of wetlands and maintain an avian phenology chart; 3) sample macroinvertebrates in small tundra ponds (subjected to experimental oil spills in 1974 and 1975) in order to assess long-term recovery rates; 4) prepare detailed cover maps of plots in Loon and Phalarope Lakes to serve as ground truth for low-level aerial photographs to be taken in August; 5) compile a species list and collection of plants found in Loon and Phalarope Lakes; 6) do vegetation line transects in Loon and Phalarope Lakes to determine frequency of occurrence of plant species; 7) record caribou movement, herd size and composition, and record Arctic fox activity; and 8) determine population levels of small mammals on four trapping grids established in 1976.

The 1978 field season extended from 4 June until 20 August. Field personnel included D.V. Derksen, D.B. McDonald and R.C. Kenyon. Snow cover

upon arrival was estimated at 75%. By 12 June snow cover was 2%. Daily weather notes were kept and a summary of these appears in Appendix 1.

I. Birds

METHODS

Large birds (loons, waterfowl, Jaegers, gulls, terns and owls) were counted each week beginning 6 June. Two observers walked abreast north and south alternately so that four passes covered the study area. Each observer canvassed an 800 meter wide corridor. In previous years only the western half of the study area (R13E, T12N; sections 13, 24 and 25) was surveyed. The addition of the eastern portion (R14E, T12N; sections 18, 19 and 30) meant that the entire study area was observed at least once a week. Figure 1 is derived from an orthophoto map of the study area. Numbers of large birds seen, and sex when known, were recorded on prepared data forms (Appendix 2).

Small birds were censused 7 June and each week thereafter by two observers on nine separate plots. The plots, established in 1972 as recorded by Bergman et al. (1977) were 200 meters wide and totalled 1.6 km^2 (Figure 1). Birds observed were recorded on prepared data forms (Appendix 3). A helicopter survey of the Kuparuk and Sagavarirktok delta areas was conducted on 8 June. The flight route was not predetermined and coverage was intended as an index of birds present in the area rather than as a systematic census. Throughout the summer daily totals of all birds seen were tallied on a prepared chronology sheet.

No formal nest searches were made but nests found during other field work

2 were marked with flagged stakes five paces north for small birds and ten paces
38 north of the nest for large birds. Nests found were periodically rechecked
for success, and for incubation period and timing of hatch when possible.

3755 000 381822 Loon nests were recorded on a separate prepared form. All nests found were
3 marked on an orthophoto map of the study area. Bird migration data was

KUP DELTA CAMP

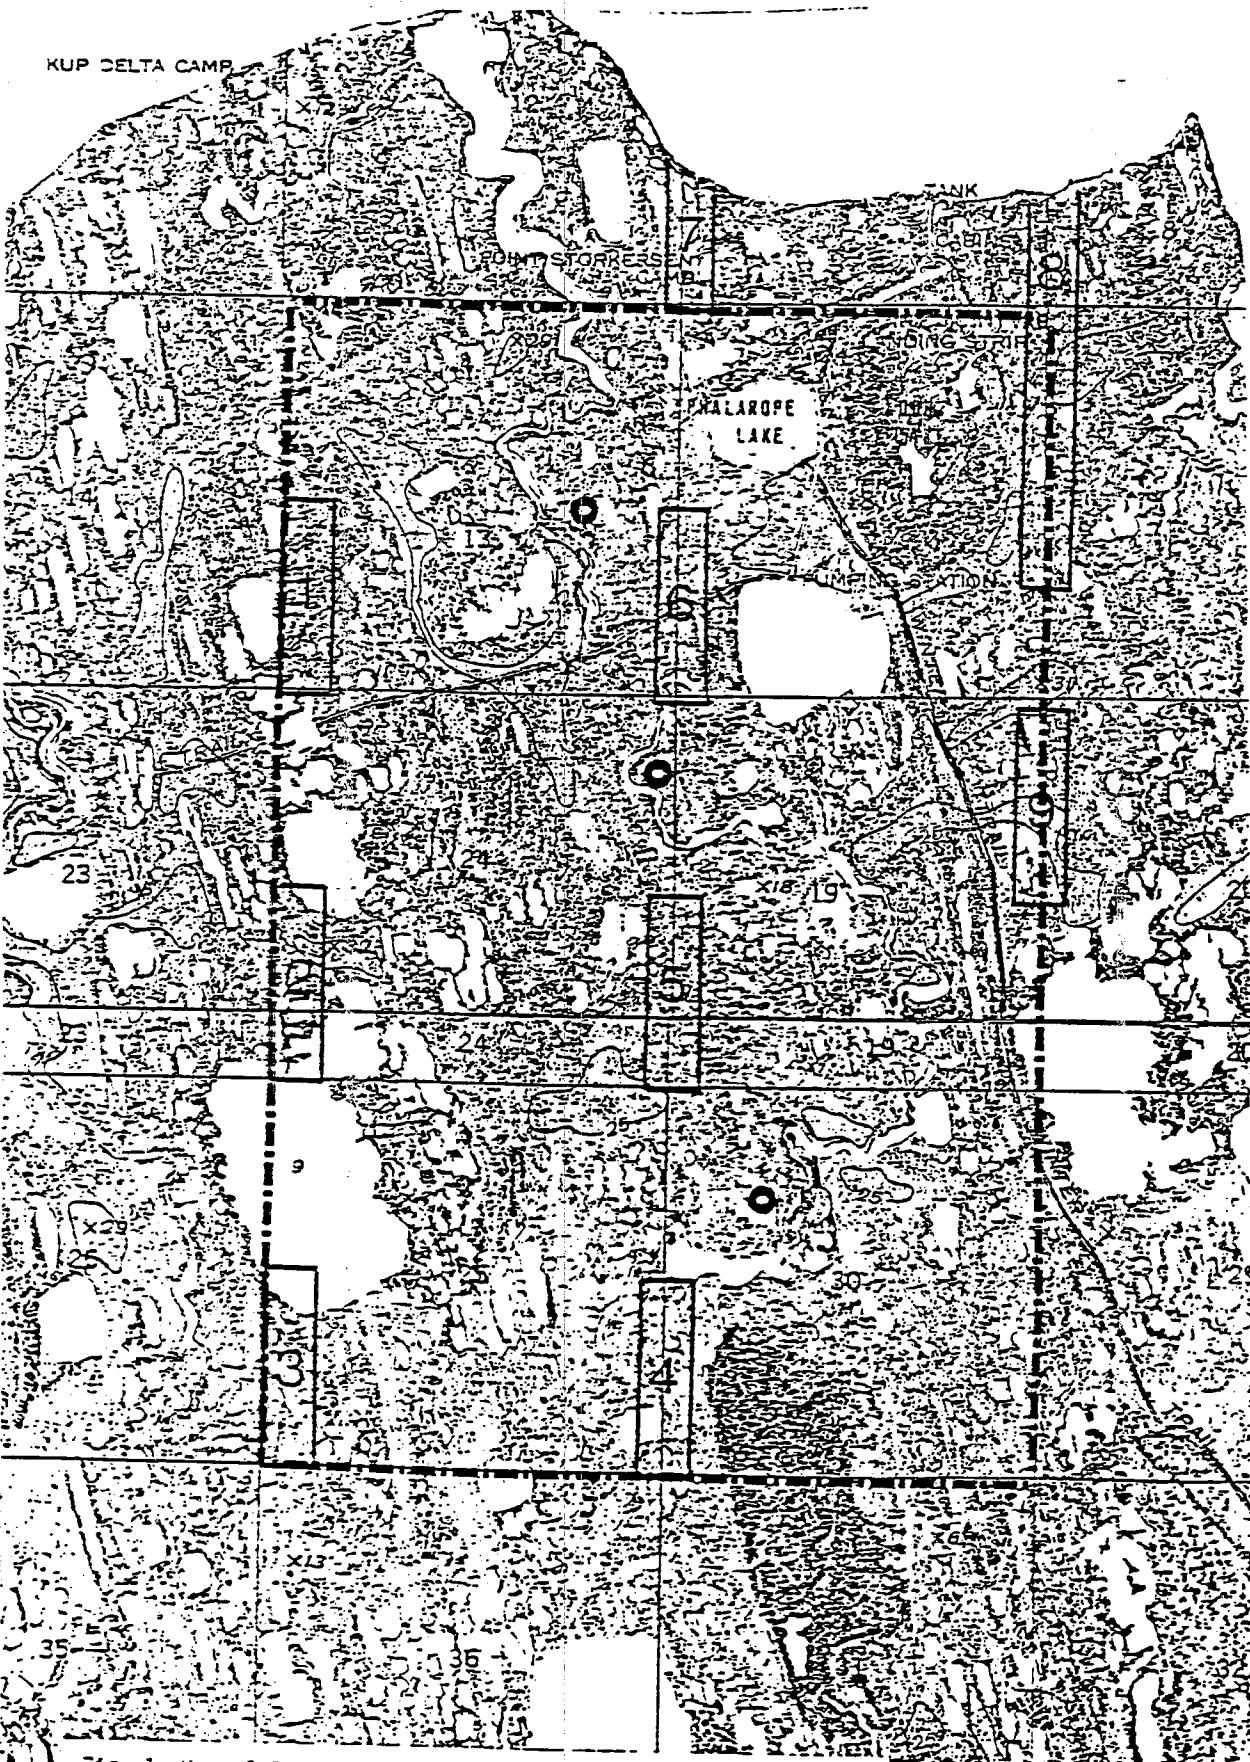

Fig. 1 Map of Storkersen Point study area showing large and small (1-9) bird survey plots, BP Pad "Z" (◆) and location of pingos (●).

obtained on an opportunistic basis. Flocks were recorded noting species, numbers, composition, and direction of movement.

Wetland use by waterbirds was recorded on prepared data sheets (appendix 4). Wetland type was noted using the categories established by Bergman et al. (1977). As shorebirds began using wetlands more heavily in the late nesting and post-nesting season they were added to the species noted on the prepared forms.

Buff-breasted Sandpiper (Tringites subruficollis) sightings were recorded. Information noted included: date, weather, location, habitat type (e.g. pingo, well-drained sedge meadow, stream-bank), number of birds seen, and activity of birds. Nest observations were conducted on two Buff-breasted Sandpiper nests. Observers sat on the ground or in a tend-blind 25-45 meters from the nest. Buff-breasted Sandpiper chicks were banded on an opportunistic basis. All birds received metal Fish and Wildlife bands and one or more red or blue plastic bands in different combinations so that each bird was individually identifiable.

RESULTS

Arrival and Snow Cover

All breeding species were present on the study area when observers arrived with the exception of loons which were not seen using the study area until 9 June (two Arctic Loons, Gavia arctica) and 10 June (thirteen Arctic Loons, six Red-throated Loons, Gavia stellata). Long-billed Dowitchers (Limnodromus scolopaceus) were not seen until 7 June, but there was no direct evidence of their nesting on the study area in 1978. Arrival dates in relation to snow cover differed somewhat for those given by Bergman et al. (1977) particularly for Buff-breasted Sandpipers (Tringites subruficollis) which were observed both earlier and with greater snow cover than in previous years. Snow cover around the Prudhoe Bay oil developments was less than 25% on 4 June, compared with 75% at Storkersen Point, probably owing to albedo

effect as suggested by Benson et al. (1975) and Bergman et al. (1977). A helicopter survey of the Kuparuk and Sagavarirktok River deltas on 3 June (Appendix 5) indicated some use by waterbirds pending ice-melt on inland lakes as noted by Bergman et al. (1977) in previous years.

Large Bird Surveys

Density estimates for breeding birds derived from large and small bird surveys appear in Table 1. Pintails (Anas acuta) were the most abundant large bird on the average. On the first survey 6 June, however, Brant (Branta bernicla) were the most abundant as flocks moved over the study area. Pintail numbers declined in the latter half of July and King Eiders (Somateria spectabilis) were the most abundant large bird on the survey of 18 July while Oldsquaws (Clangula hyemalis) were the most abundant bird on 25 July. Numbers of King Eiders and Oldsquaws peaked in mid-June and fluctuated at lower levels through the summer as non-breeders or late migrants moved on, males left the study area and unsuccessful nesters left for their molt. Numbers increased at certain times due to brood sightings and, in the case of Oldsquaws, sightings of birds molting in large class V lakes. White-fronted Geese (Anser albifrons) were most abundant when observers arrived, declined steadily such that they were absent from three consecutive surveys in late July and early August, and then increased in August as post-molting birds began staging in wetlands on the study area.

Small Bird Surveys

Density estimates for shorebirds derived from small bird surveys indicate that Red Phalaropes (Phalaropus fulicarius) were the most abundant shorebird on the average followed by Pectoral Sandpiper (Calidris melanotos), Semipalmated Sandpiper (Calidris pusillus) and Dunlin (Calidris alpina). Relative abundance fluctuated with Red Phalaropes most abundant on five surveys, Dunlins

on three surveys, Pectorals on two and Semipalmated Sandpipers most abundant on one survey in which they outnumbered the combined total of the other three. No definite decrease in numbers was noted in late July and early August as in previous years (Derkson et al. 1976, Heinz and Koob 1977). Rather, distribution appeared to be clumped in the post-nesting period as shorebirds gathered at drying class II wetlands (small shallow ponds). The relative abundance of the four most common shorebirds is shown in Figure 2. Lapland Longspurs (Calcarius lapponicus) were the most abundant bird on six of the eleven surveys. They were the most abundant bird on the average of censuses and were always the most abundant passerine.

Non-breeding Birds

A single Peregrine Falcon (Falco peregrinus) was seen very briefly 17 July as it flew eastward between the camp buildings and the coast. Appendix 6 shows the daily tally for all birds seen. Details of unusual sightings for the 1978 season are on file with the University of Alaska Museum.

Nest, Clutch and Brood Data

One hundred and two nests of 23 species were found during the field season. Clutch and success data appear in Table 2 and Appendix 7. Loon nests were not approached so as to minimize disturbance. Loon nests and broods sighted are shown in Figure 3. A Canada Goose (Branta canadensis) nest on an island in a class V (deep open) lake was a new breeding record for Storkersen Point as were two Hoary Redpoll (Acanthis hornemannii) nests around the buildings at camp. A White-rumped Sandpiper (Calidris fuscicollis) with two downy young, observed on the small bird survey of 12 July, also constituted a new breeding record for Storkersen Point. Breeding behavior (courtship or distraction displays, agitated circling) was observed on two occasions in the same location for Long-billed Dowitchers (Limnodromus scolopacoides) and on

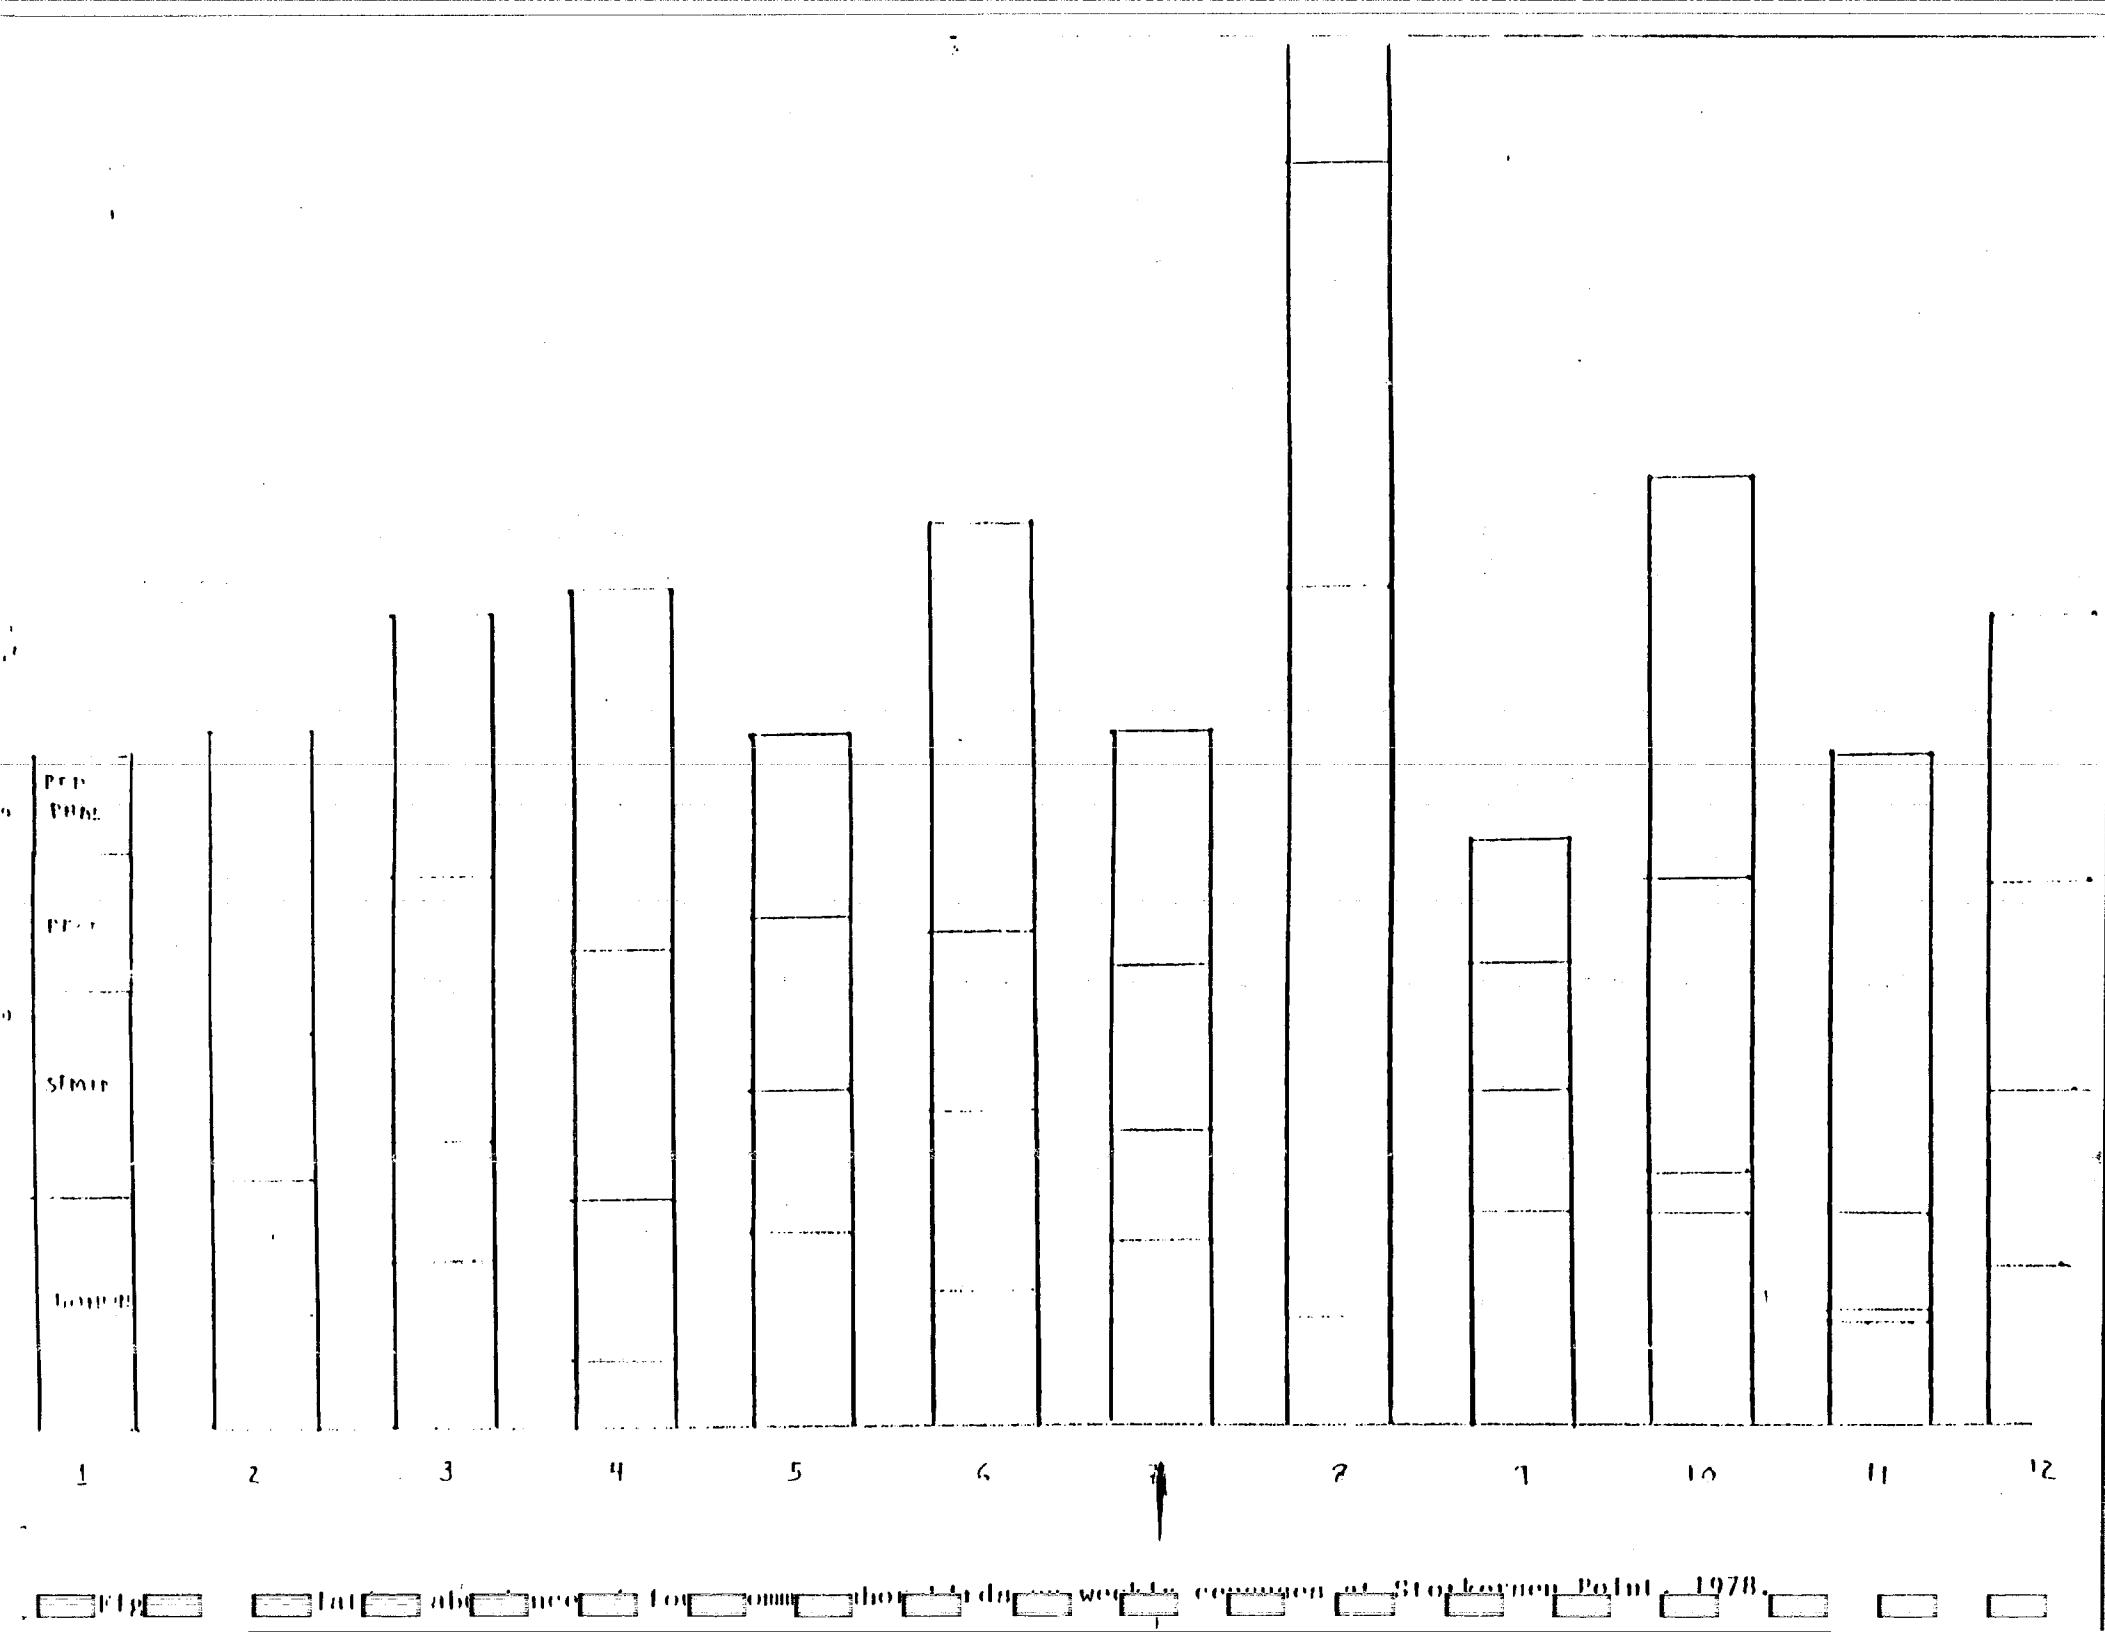

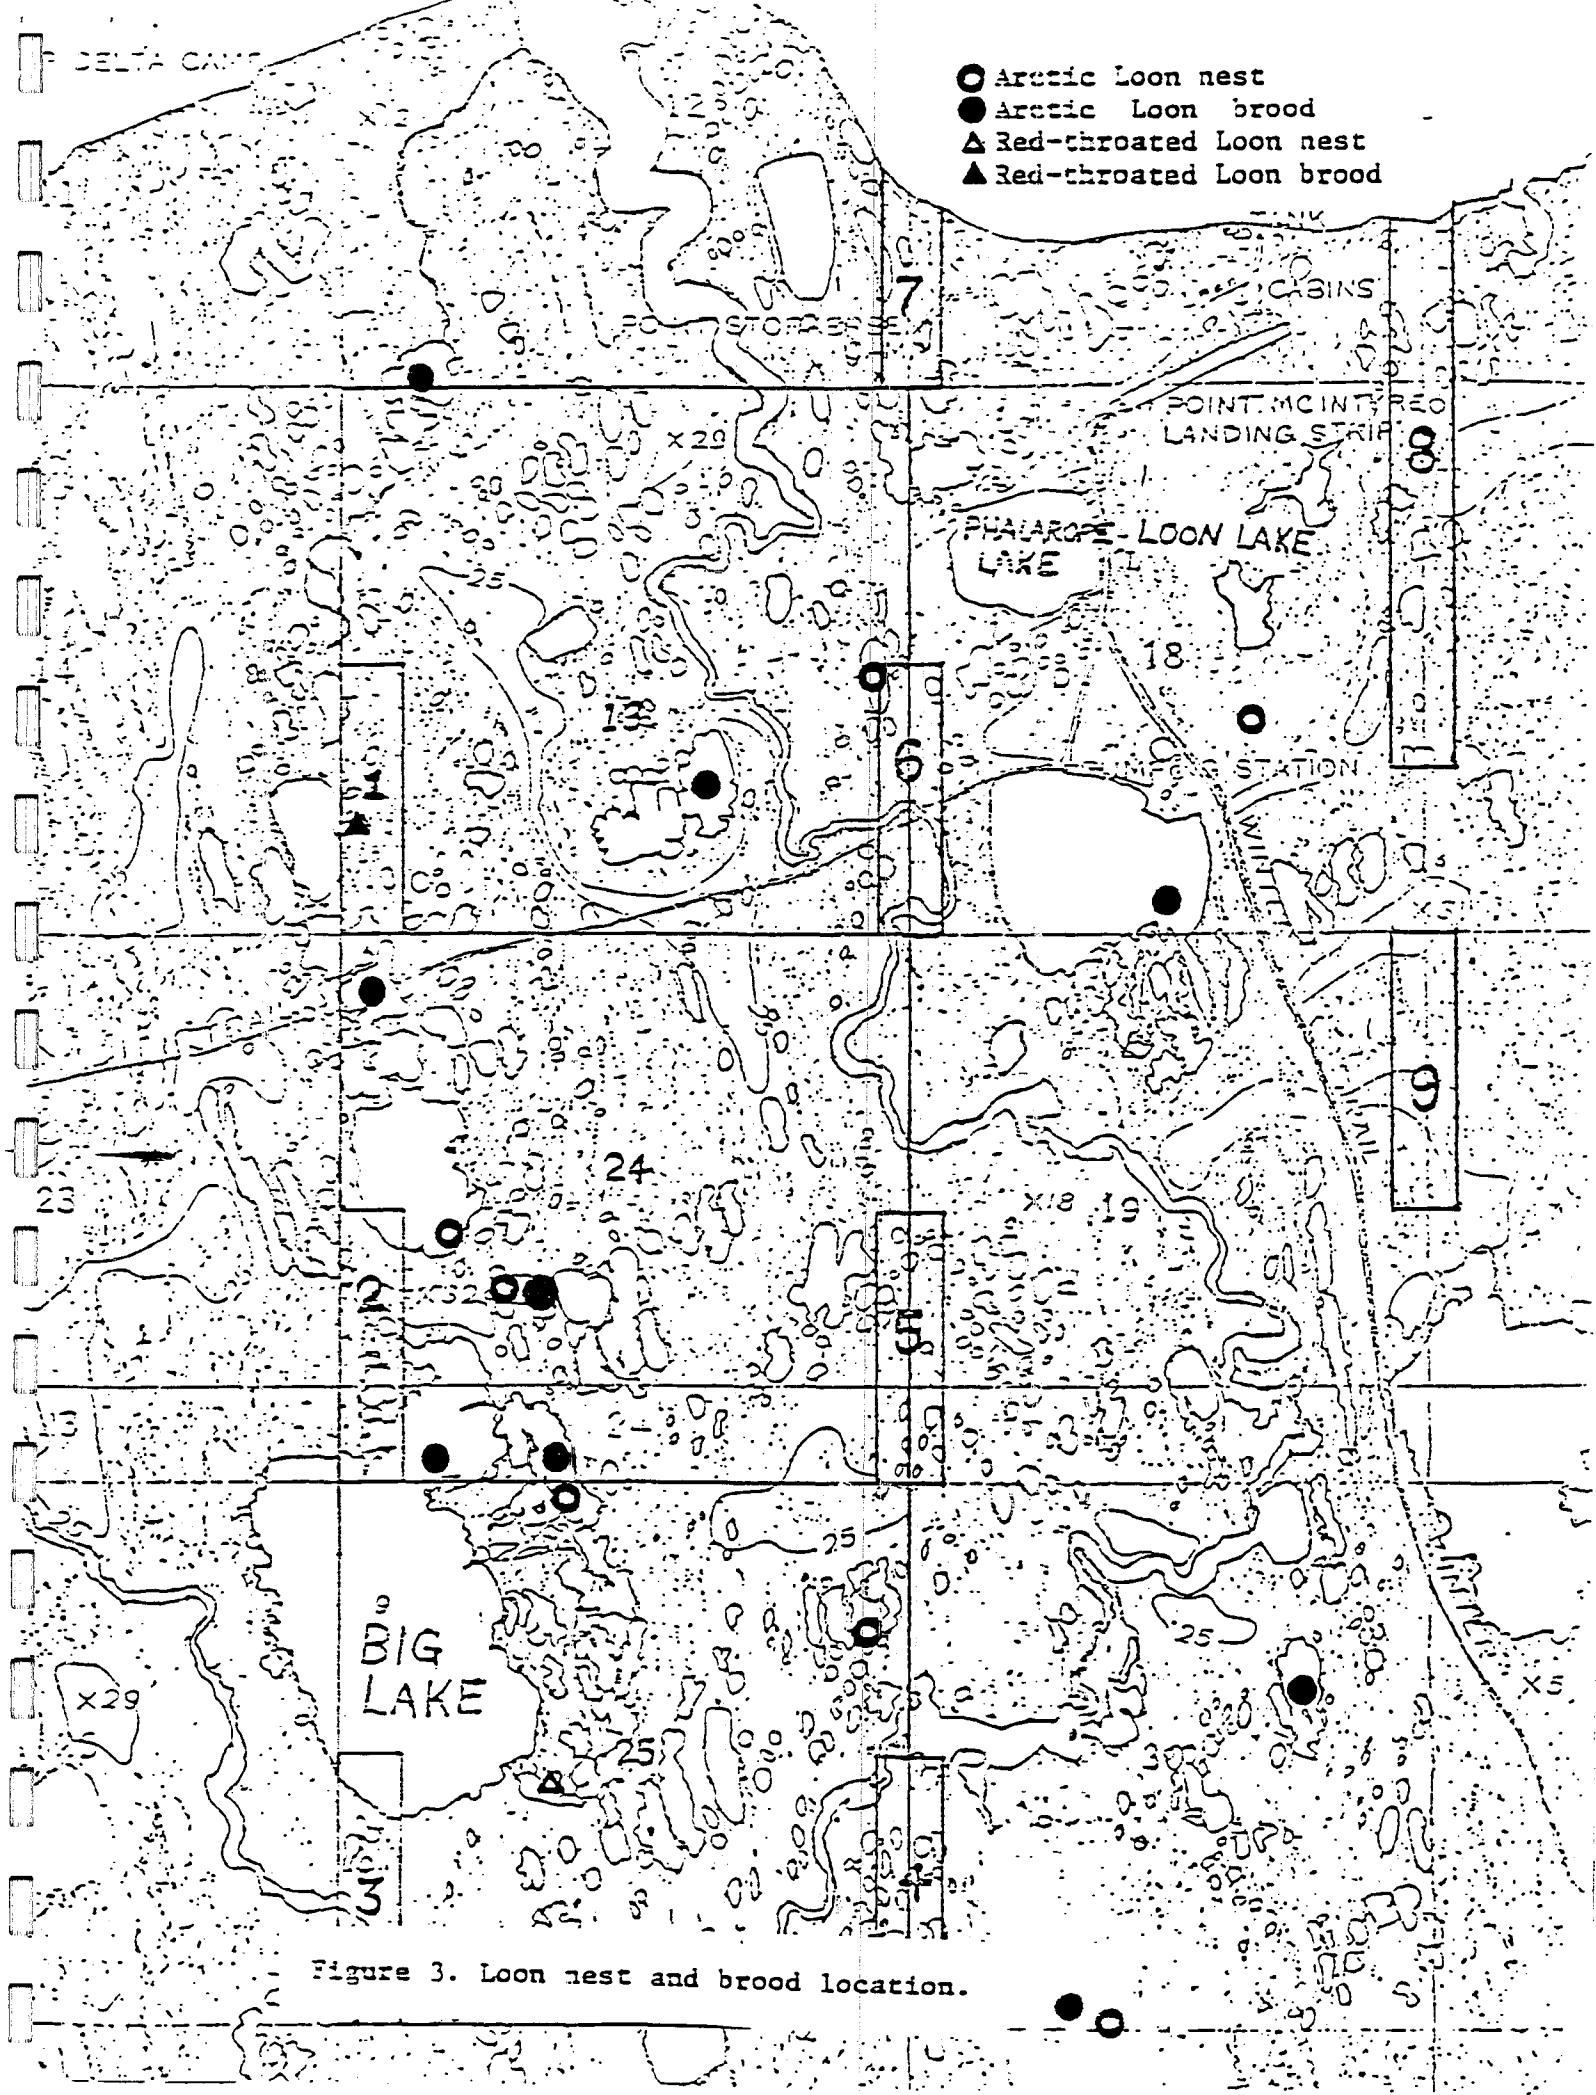

Table 1. Nest data compilation for Storkersen Point, 1978.

Species	Number of nests	Nest number from form	Range of Clutch size	Range of initiation dates	Range of hatching dates	% success	Remarks
Canada goose	1	42	3	-	7/12-7/13	100	New breeding species for Storkersen Point
White-fronted goose	3	18, 25, 37	4, 2, 3	-	-	0	All clutches may have been incomplete
Oldsquaw	6	55, 58, 38, 39	2, 1, 0, 0	-	-	0	One nest abandoned before laying, one after 2 eggs laid
King eider	7	26, 27, 53, 61, 74, 78, 92	5, 4, 1	6/17-7/8	7/15-7/23	43	Most hens not flushed
Spectacled eider	2	39, 40	5, 5	-	-	0	
American golden plover	4	21, 45, 33, 34	2, 4, 4, 4	-	7/12-7/25	67	Two egg clutch was complete but evaluation inconclusive
Black-bellied plover	2	64, 73	4, 4	-	7/15	50	
Ruddy turnstone	3	15, 16, 30	4, 4, 4	-	7/2	100	
Northern phalarope	2	70, 93	4, 4	-	7/17	100	
Red phalarope	9	5, 9, 22, 29, 66, 68, 72, 36, 91	6 (8), 3 (1)	6/11-6/17	7/2-7/8	50	2 success based on 5 nests 4 had insufficient data
Semipalmented sandpiper	7	2, 4, 19, 28, 33, 44, 51	All 4	-	7/3	50	2 success based on 5 nests 2 had insufficient data
Baird's sandpiper	10	7, 24, 31, 43, 46, 47, 54, 67, 77, 85	All 4	6/11	7/3-7/29	100	One had insufficient data
Pectoral sandpiper	1	62	4	-	7/16	100	Chick and pipped egg photograph taken
Dunlin	5	37, 38, 50, 50, 79	All 4	-	-	100	Based on 4 nests, 1 had insufficient data
Buff-breasted sandpiper	6	59, 65, 80, 81, 82, 90	All 4	-	7/12-7/24	100	See specific nest form
Parasitic jaeger	1	35	2	-	-	0	Another pair nested and failed, nest never checked
Long-tailed jaeger	1	17	2	-	-	0	
Glaucous gull	1	41	3	-	Between 7/8 and 7/14	100	
Heary sandpiper	2	56, 73	3, 3	7/3 (1)	Before 6/30 ~ 7/12	100	First nesting records for Storkersen Point
Lapland longspur	17	1, 3, 6, 3, 10, 11, 12, 14, 20, 32, 34, 28, 49, 52, 57, 63, 69	30 (2), 5 (9), 6 (3) 0 (2), 3 (1)	6/9 (1) 6/10 (1)	6/25-between 7/5 and 7/12	53	One late 3 egg clutch was successful
Snow bunting	5	13, 23, 36, 71,	4, 5, 6, 7	6/12 (1)	Before 7/11	60	
21 species	93			6/11-7/3	6/25-7/26	57	Success - 53 nests Failure - 27 nests Insufficient data - 11 nests

14

several occasions at scattered locations for Willow Ptarmigan (Lagopus lagopus). No other species were believed to have nested at Storkersen Point in 1978 except those species listed above and those for which nests were found. Whistling Swans (Olor columbianus) which have nested in previous years, used study area wetlands regularly and a pair, including a collared individual (light blue collar, yellow characters: A-blank-7-5), molted on a class V (large open) lake which adjoined a large class IV (deep-Arctophila) lake. Brant (Branta bernicla) also noted as a breeding bird in previous years, were not seen on the study area after late June although a few broods were seen along the coast east and west of the study area. Pintails (Anas acuta) were notably less abundant than in 1977 - the census average for 1977 was 14.10 birds/km² while in 1978 it was 6.17 birds/km². No Pintail nests were found and no broods were seen. Heinz and Koob (1977) noted a Rock Ptarmigan (Lagopus mutus) brood but in 1978 two males in winter plumage circling the cabins on 11 June were the only Rock Ptarmigan seen.

Migration

Data from migration forms (Appendix 8) indicate that peaks of movement were most noticeable for Brant (Branta bernicla), Oldsquaws (Clangula hyemalis), Pomarine Jaegers (Stercorarius pomarinus) and Golden Plovers (Pluvialis dominica). Brant moved both east and west across the study area and along the coast from observer arrival on 5 June until 8 July. Much of the movement appeared to be local movements of flocks moving back and forth between feeding areas. Flocks were noticed as much as three miles inland which may have been owing to the fact that there was still sea ice over the Beaufort Sea. Between 8 July and 17 August no Brant flocks were seen although Brant broods were sighted as noted above. On 17 August a heavy westward movement began which continued until observers left on 20 August. In August Brant flocks were sighted moving only along the coast or over the Beaufort Sea and not

inland. They were moving westward in all cases. Flocks of several hundred birds used coastal wetlands east of the study area and to the west in the Kuparuk River delta area. D.V. Derksen saw Brant still moving westward on a brief visit to Storkersen Point.

Oldsquaws moved along the coast in small groups (<10) during June and until mid-July. The preponderance of movement was eastward but westward movement was also observed. Beginning on 17 July and continuing until 2 August a generally westward movement was noted with as many as 168 birds counted per day. During July Oldsquaw rafts were noted along the barrier islands. A heavy driftline of feathers indicated that these were breeding birds. Oldsquaw numbers were low both on the study area and in salt water during August.

Pomarine Jaegers moved through the study area from observer arrival on 5 June until 28 June after which there were only two more sightings, the last, on 13 July, of a single bird. No direction of movement prevailed. Golden Plovers were observed moving east on three days between 26 July and 5 August. On 18 August 75 birds were seen in six flocks averaging 12 birds. One hundred and seventy-seven birds were noted on 19 August in 12 flocks. The great majority appeared to be birds of the year and some birds were seen flying with Black-bellied Plovers (Pluvialis squatarola) whose movements coincided closely with those of Golden Plovers although totals were always lower.

Wetland Use

A summary of wetland use data appears in Appendix 9. The following narrative summary of bird use of wetlands uses the classification developed by Bergman et-al. (1977) which is summarized in Appendix 9. Conclusions are drawn from wetland use forms and other observations by field personnel.

Class I (flooded tundra): Phalaropes fed in these wetlands and they were used by Pintails and other waterfowl before other wetlands melted.

Class II (shallow Carex ponds): These wetlands received heavy use in the post-nesting season. Phalaropes and Pintails fed in the waters in which macroinvertebrates were concentrated by lowering water levels as noted by Bergman et al. (1977). In late July shorebirds began feeding heavily along the drying edges of these ponds. An influx of Stilt Sandpipers (Micropalama humanopus) occurred in August. Flocks of 5-15 birds were noted on class II wetlands throughout the study area. Plovers, Pectoral Sandpipers (Calidris melanotos), Dunlin (Calidris alpina) and Semipalmated Sandpipers (Calidris pusillus) also used class II wetlands after mid-July.

Class III (shallow-Arctophila): Pintails and phalaropes used these wetlands fairly heavily. On 1 July a flock of 102 Red Phalaropes (Phalaropus fulicarius) was noted on a class III pond and young of the year used these ponds for food and cover. Oldsquaws (Clangula hyemalis), Eiders (Somateria sp.) and Loons (Gavia sp.) also used class III wetlands throughout the summer.

Class IV (deep Arctophila): These wetlands were important feeding and resting areas for Arctic Loons (Gavia arctica). Four of seven nests and seven of nine broods sighted were on class IV wetlands. Eiders used class IV wetlands throughout the reproductive cycle as noted by Bergman et al. (1977). Both of the two Spectacled Eider (Somateria fischeri) nests and the only Glaucous Gull (Larus hyperboreus) nest found on the study area were located on islands in the same class IV wetland. Oldsquaws, Pintails and Red Phalaropes were also noted as using these wetlands.

Class V (deep open): Whistling Swans (Olor columbianus), Canada Geese (Branta canadensis) and Oldsquaws molted on class V lakes on or adjacent to the study area. On 7 August 79 Canada Geese, including flightless adults and at least one brood, were seen using a series of class V lakes south and east of the study area. The first Canada Goose nest found at Storkersen Point was on an island in Pump Lake, a class V wetland. This same lake served as

a feeding and loafing ground for Arctic Loons (Gavia arctica) which were seen in groups of up to 11 birds. An Arctic Loon brood was seen on the lake and Red-throated Loons (Gavia stellata) were observed there on occasion.

Class VI (basin complex): Sixty-four percent of all Pintails observed using wetlands were seen in basin complexes. Paired King Eiders (Somateria spectabilis) used basins extensively during the first half of June. Red-throated Loons may have nested in a basin complex on the study area and were frequently noted using these wetlands. Phalaropes used class VI wetlands next most heavily after class II ponds. During the latter half of July and into August Pectoral Sandpipers (Calidris melanotos) and Red Phalaropes (Phalaropus fulicarius) flocked and fed in basins and Long-billed Dowitchers (Limnodromus scolopaceus), Plovers (Pluvialis sp.) and Dunlin (Calidris alpina) also used these wetlands. Whistling Swans (Olor columbianus) were observed feeding in Carex/Arcophila beds fairly frequently. Staging White-fronted Geese (Anser albifrons) grazed heavily in Carex beds in Loon Lake, and probably in other basin complexes on the study area, during the last few days of the field season.

Class VII (beaded stream): Arctic Loons (Gavia arctica) and Oldsquaws (Clangula hyemalis) were frequently sighted along Fawn Creek. Eiders and Pintails also used class VII wetlands particularly flooded portions and areas vegetated by Arcophila. Phalaropes fed along flooded edges early in the season. Shoreline feeding by Phalaropes and Semipalmated Sandpipers (Calidris pusillus) occurred from the creek mouth to more than a mile upstream during periods of low water in late July. This zone was affected by tide and was measurably brackish (T. Rothe USFWS, vocal communication).

Class VIII (coastal wetlands): Coastal wetlands were used extensively by Brant in both spring and fall. Spring movement appeared to include local flights from one feeding ground to another. Fall movement, which began on 17 August, was exclusively westward but flocks of up to 200 birds stopped to

feed at coastal wetlands adjacent to the study area. Shorebirds also used coastal wetlands late in the season. Semipalmated Sandpipers, Stilt Sandpipers, White-rumped Sandpipers and Dunlins were observed using brackish ponds and lagoons. On 18 August a flock of 52 Dunlin was seen feeding at the mouth of a creek east of the study area.

Beaufort Sea: All four species of Loons were observed on the waters of the Beaufort Sea during the summer. Arctic and Red-throated Loons were often seen carrying food items inland from the bay. Rafts of sea ducks, presumably mostly Oldsquaws, were seen out by the barrier islands in July but were usually too distant for positive identification. On 20 July 45 Glaucous Gulls (Larus hyperboreus) were observed feeding very actively within 500 meters of shore. On 18 August 52 Glaucous Gulls were observed following an Eskimo fishing boat and they were later seen loafing on a barrier island. Gulls were regularly seen along the barrier islands and small numbers flew the coastline on most days. Small numbers of King Eiders and Oldsquaws were seen on inshore waters (< 1 km) from time to time and Common Eider flocks of up to 34 birds were seen on several occasions flying across the bay. Small groups (< 15) of Red Phalaropes used the surf-zone in August but no large flocks were seen on salt water. When disturbed Brant moved from coastal spits and wetlands out into the bay with their broods.

Buff-breasted Sandpiper (Tryngites subruficollis) observations: Two hundred and forty-nine sightings of Buff-breasted Sandpipers were recorded on prepared forms. Locations of single and double wing displays are plotted on an orthophoto map in Appendix 10. The displays are concentrated along Fawn Creek particularly in the area around the two pingos which rise from the high, dry stream-bank in sections 24 and 13. The affinity of displaying birds for dry raised areas is clearly demonstrated by this distribution. The combined total of displays for sections 18, 25 and 30 is 14. The total for

10

sections 13, 19 and 24 is 56. The first three each have extensive wetlands including basin complexes and deep open lakes; they also have little high, dry stream-bank and the pingo in section 30 is bounded on three sides by moist tundra. The second three sections have less extensive wetlands and contain most of the high dry streambank habitat as well as two pingos surrounded by dry tundra or streambank. Buff-breasted Sandpipers were never seen feeding in ponds or at pond margins but exclusively on dry ridges, dry meadows or well-maintained raised areas such as pingos or streambanks.

Two Buff-breasted Sandpiper nests were watched for a total of approximately 50 hours, including one continuous 24 hour watch. For the majority of the time the incubating birds were visible on the nest. General conclusions include the following: 1) only one bird presumably the female incubated the eggs; 2) with one exception the bird flew off the nest and zig-zagged back on foot as much as 50 meters and never less than 5 meters; 3) foraging distances were usually less than 250 meters and foraging habitat was typical of the species - dry ridges of polygons, streambanks, dry meadows; 4) attendance ranged from as little as 10 minutes at mid-day to almost three hours during the night when temperatures were lower and light intensity decreased.

Twenty-seven Buff-breasted Sandpiper chicks were banded with metal USFWS bands and various combinations of red and blue plastic bands. A list of band combinations and a map of banding locations is given in Appendix II. It is worth noting that 18 of the banded birds and three of the nests were located in a zone one half mile wide by one mile long (north - south). Since coverage of the study area was generally fairly uniform this was not felt to be an artifact of observer effort. The apparent grouping is not centered on the display grounds and may reflect a habitat/resource partitioning as suggested by Pitelka et al. (1974). This zone is delineated on the orthophoto map in Appendix II.

II. Aquatic macroinvertebrate sampling

METHODS

Six experimentally oiled ponds, three oiled in 1974 and three oiled in 1975, three established control ponds (Abraham 1975) and a contaminated pond near Storkersen Well were sampled for aquatic macroinvertebrates. Each pond was sampled four times during the summer, 22-24 June, 30 June - 2 July, 13-15 July and 27-29 July. Techniques used to sample the ponds were identical to those used by Howard (1974) and Abraham (1975). Macroinvertebrates were tentatively identified, counted and stored in a 5% formalin solution. Temperature, pH and specific conductivity were measured in each pond at the time of sampling. Temperature was measured with a hand held thermometer, pH was measured with a Hach Chemical Company Kit and specific conductivity was measured with a Hatch Conductivity Meter. During the fourth sampling period, 27-29 July, temperature and specific conductivity were measured with a Yellowsprings Model conductivity meter.

Notes were taken on all ponds noting ice cover, water clarity, amount of oil present or released from sediments, vegetative growth characteristics, wind effects, and drainage to other wetlands. Pond notes were taken on 9, 15, 22-24 June, 13-15 July and 14 August. Black and white photographs of the control and experimentally oiled ponds were exposed twice during the summer on 11 June and 15 July.

Samples of surface water and bottom sediments were taken from Storkersen Well Pond on 19 August. These samples are to be analyzed to determine the amount of hydrocarbons and heavy metals present in this pond.

The six oiled ponds and three control ponds were marked permanently with metal tags and stakes for future reference. Stakes were placed on the north shore of each pond.

RESULTS

The physical and chemical characteristics of the experimental ponds are given in Table 3. Nineteen taxa of macroinvertebrates were found in control ponds in 1973 (Table 4). Nineteen taxa were also found in ponds oiled in 1974, while only ten taxa were found in ponds oiled in 1975. Taxa found in ponds oiled in 1974 were similar to those found in control ponds, but numbers of invertebrates found were lower (Figure 4). Cladocera, an abundant taxa in 1974 oiled ponds and control ponds, were not found in 1975 oiled ponds. A single Plecoptera nymph was found in a 1975 oiled pond. Plecoptera have not been found in ponds oiled in 1975 in previous years. Total numbers of invertebrates collected in each of the three types of ponds are shown in Figure 2. Numbers of macroinvertebrates found in control and 1975 oiled ponds are consistent with those found by Heinz and Koob (1977), but numbers of invertebrates found in ponds oiled in 1974 were considerably lower than those found in 1977 (Heinz and Koob 1977). A complete listing of the numbers of invertebrates collected from the nine experimental ponds and Storkersen Well pond during each sampling period is presented in Appendix 12.

III. Vegetation analysis in Loon and Phalarope Lakes

METHODS

A collection of the vascular plants found in Loon and Phalarope Lakes was made. Depth of water, if present, and location within the lake basin was noted. Plants were identified with the help of Hulten (1968). Seven to ten specimens of each species found were pressed and dried to preserve them for verification and future use.

Vegetation line transects 400 and 200 m long were established in Loon and Phalarope Lakes respectively (Figure 5). Both transects were set up parallel to the road that divides the two class VI basin complexes. A 100 m

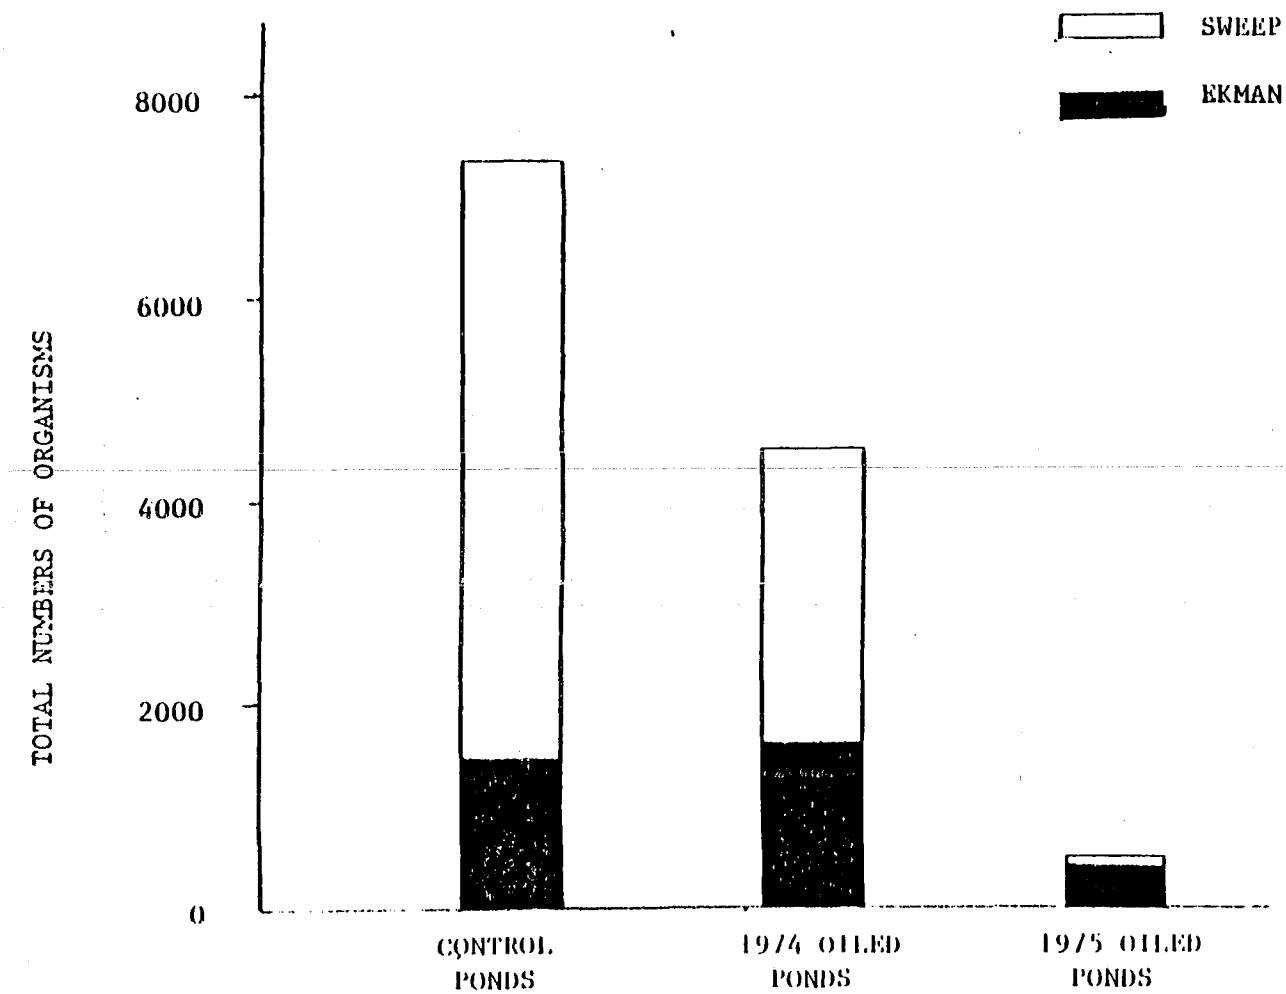

Fig. 4. Total number of macroinvertebrates collected in sweep and Ekman samples at Storkersen Point in 1978.

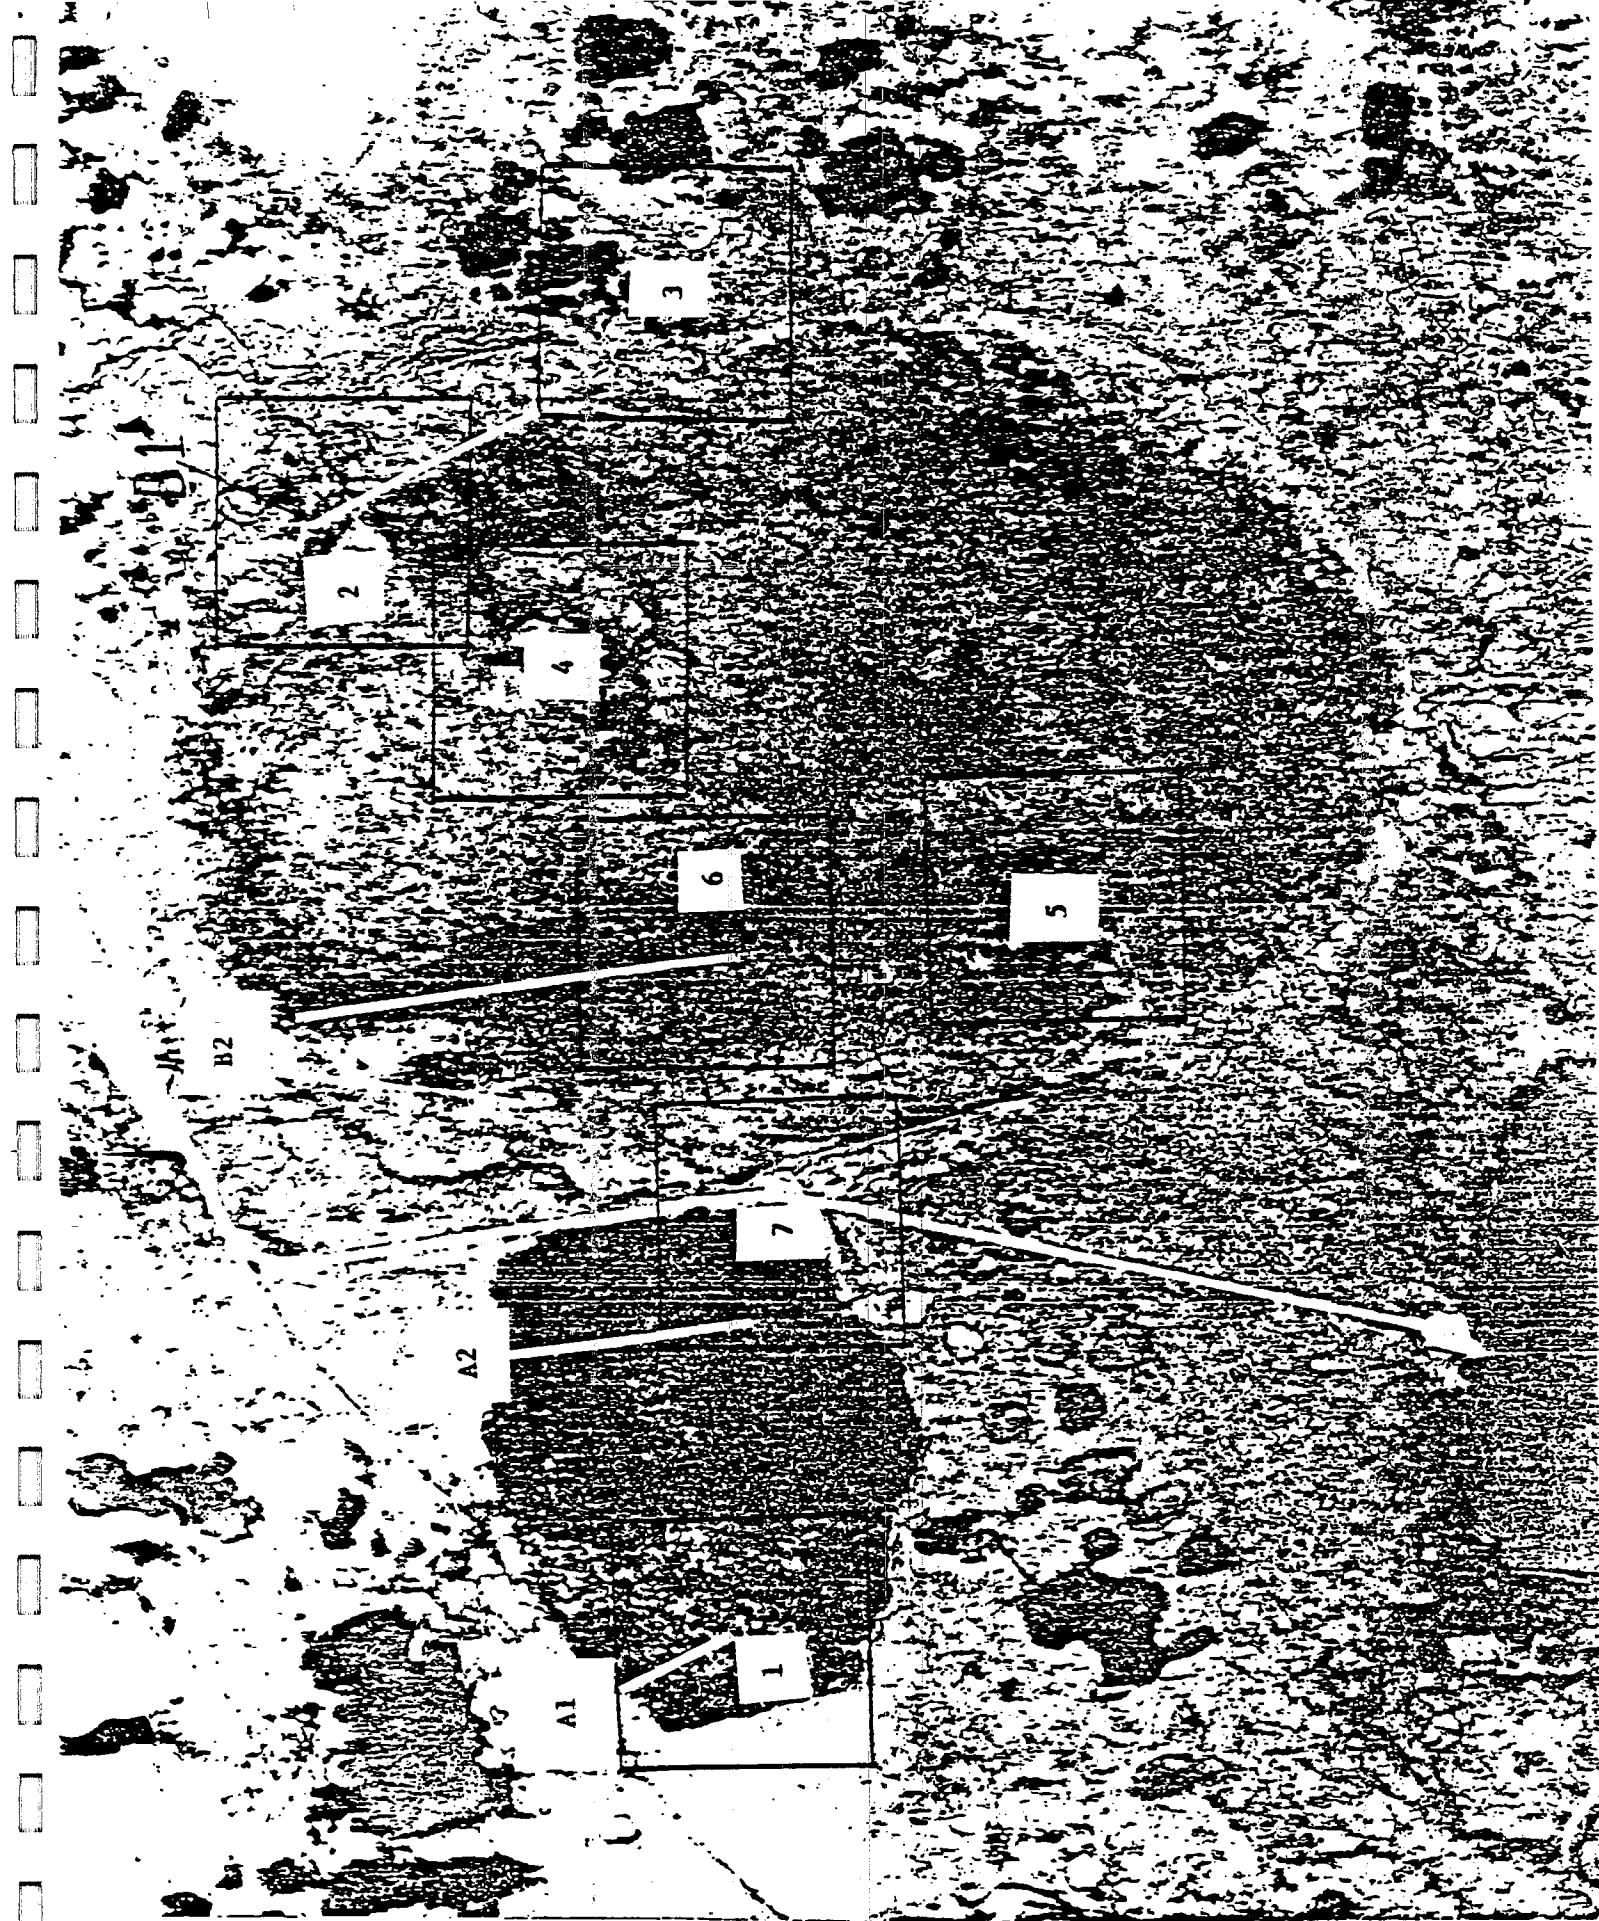

Fig. 5. Location of trend plots (1-7), Phalarope (A1-2)
and Loon (B1-2) Lake vegetation line transects.

transect established in Loon Lake (Heinz and Koob 1977) was extended to 200 m. Four vegetation line transects were sampled at one meter intervals. Plant species (if present), water depth and depth of bottom sediments were recorded on prepared data sheets. Line transects were sampled in Phalarope and Loon Lakes on 3 and 4 August, respectively.

Black and white 35mm photographs of Loon and Phalarope Lakes were exposed to record ice and snow melt, changes in water depth and vegetation. A series of photographs of each basin were taken from a predetermined location each week.

Three of the seven trend plots established in 1977 (Heinz and Koob 1977) in Loon and Phalarope Lakes were cover mapped in the field. These cover maps are to serve as ground truth for low level aerial photography executed on 17 August. Cover mapping was done using a vegetation classification system developed by Webber and Walker (1975) with modifications by Markon (1977) and Heinz and Koob (1977). Techniques used to cover map trend plots in the field were identical to those used by Heinz and Koob (1977). The two north corners of all trend plots were permanently marked with metal stakes for future reference.

RESULTS

Vascular plants found in and collected from Loon and Phalarope Lakes and their relative abundance are presented in Table 5. Results of the vegetation line transect sampling are presented in Table 6. Diversity of plant species was found to be lower in Phalarope Lake, where normal drainage is blocked by a road constructed when the D.E.W.-line site was in operation, than in Loon Lake where drainage is not restricted.

IV. Mammal observations

METHODS

Small mammals were trapped on four grids established by Derksen et al.

(1976), to compare populations on high-center polygon and upland tundra areas. Grids, trap locations and baiting techniques were identical to those described by Derksen et al. (1976) and Heinz and Koob (1977). Grids A1 and A2 (Figure 6) were tapped from 28 June to 5 July. Traps were checked twice daily for a total of 672 trap nights. Traps on grids B1 and B2 were checked twice daily from 17-22 July for a total of 576 trap nights. Snapped traps and signs of lemming hair or removal by predators was noted.

Arctic Fox (Alopex lagopus) dens were located from Derksen et al. (1976) and field observations. Activity and food items found at den sites were noted. Observations of fox during regular field work were recorded to get home range information.

Caribou (Rangifer sp.) herd size, composition, and movement were noted.

RESULTS

No lemmings were trapped on the four grids. Fourteen and 13 snapped traps were found on high center polygon and upland tundra grids, respectively. One snapped trap, from a high center polygon area (Grid A1), contained traces of lemming hair. One Lapland Longspur was trapped. Nine lemmings, three Green-collared Lemmings (Dicrostonyx groenlandicus), three brown lemmings (Lemmus trimucronatus), and three unidentified lemmings, were seen on the study area during daily field work.

Five active Arctic Fox dens were found on and near the study areas (Figure 7). Pups were observed at all dens except one, where fresh digging, scats, food items and adult animals were observed. Food items identified at active den sites included remains of Arctic Loon, White-fronted Goose, King Eider, Oldsquaw, unidentified waterfowl, waterfowl eggs, Lapland Longspur, lemmings, Arctic Ground Squirrel (Spermophilus parvus) and caribou. A Fish and Wildlife Service leg band was found on the leg of a White-fronted Goose at an active fox den.

Caribou were observed on the study area in small groups (1-20) through June and most of July. Larger herds (30-100) were observed on warm days in July when mosquitoes caused the caribou to move along the coast. Herd size increased in late July and early August (100-500). Through the remainder of August only small groups (1-15) were observed. Caribou movement across the study area seemed random. No patterns in herd composition were seen during the summer. Observations of neck-collared caribou are presented in Appendix 13.

DISCUSSION

The Alaska Pipeline was completed in 1977. Oil development activities were scheduled to encroach on the Storkersen Point study area in 1978 but had not done so by the end of the 1978 field season. During July and August, however, heavy barge traffic included many modular buildings for expansion of existing developments. Further construction could create more wetland changes such as those that have occurred in Phalarope Lake which resulted in lower plant species diversity and different bird use patterns.

Macroinvertebrate sampling in experimentally oiled ponds indicated that effects of spills were most pronounced for column-dwellers and less drastic for benthic organisms. Four years after initial spillage oiled ponds still had lower numbers of column-dwellers although benthic numbers and total taxa were comparable. Three year old spills, all of which involved larger initial doses, showed highly depressed column-dweller populations, significantly lower benthic populations, and just over 50% of the taxa when compared to control ponds. The extremely heavy accidental spill at Storkersen Well pond still had not allowed any column-dwellers to return after 11 years and only a very few benthic organisms, all apparently one species of Tendipedae, were found. Both oil spills and construction effects would have their most deleterious effects on basin complexes (Bergman's Class VI). These effects would be due to the large size of the complexes and their heavy use by many species such as

Pintails, Geese and shorebirds. Shorebirds were seen probing in weathered oil on Storkersen Well pond indicating that birds might undergo primary effects by contact as well as secondary effects through depletion of macroinvertebrate food resources such as those shown above.

65	D Buff-breasted Sandpiper	7/2/78	4	O.K. 7/12/78 - 1 egg 7/14/78
66	D Red Phalarope	7/2/78	1	1 egg lost 7/7/78 Success 1 unhatched egg (eaten) ✗
67	D Santa Sandpiper	6/29/78	4	7/15 no eggs, no sign of predation or hatch - checked 7/4 o.k. ○
68	B Red Phalarope	7/3/78	4	
69	B Lapland Longspur	7/3/78	3	7/12 5 downy young ✓
70	D Northern Phalarope	7/4/78	4	7/15/78 o.k. No eggs 7/18/78 attributed advection
71	B Snow Bunting	7/5/78	4	7/12 Downy young in nest
72	D Red Phalarope	7/5/78	3	No eggs 7/12/78. A few feathers eaten. Presumed SUCCESS
73	D Black-bellied Plover	7/5/78	4	O.K. 7/12/78 2 downy young 2 eggs 7/15/78 ✓
74	D King Eider	7/7/78	(3 young)	Not hatched, o.k. 7/14/78. 3 dead seen 7/15/78 new have been
75	D Hoary Puffin	7/3/78		Not hatched Successful, hatched
76	B Snow Bunting	7/7/78	5	Downy young 7/12/78 SUCCESS ✓
77	B Baird's sandpiper	7/9/78	4	O.K. 7/11/78 - o.k. 7/16, FE or FT No eggs 7/24 Presume success
78	B King eider	7/11/78	5	7/18 - Unsuccessful - predation unknown predator, no eggs seen success 7/14/78 o.k.
79	D Dunlin	7/10/78	4	
80	D Buff-breasted Sandpiper	7/11/78	4 Downy YOUNG	STILL IN NEST, PICTURES TAKEN ✓
81	D Buff-breasted Sandpiper	7/12/78	4	4 eggs all apparently pipped = 15:40
82	D Buff-breasted Sandpiper	7/12/78	4	7/16 o.k. 7/23 ex. 7/24 Hatched, eggs gone ✓
83	B American Golden Plover	7/12/78	4	4 downy young - 3 eggs 1 dead chick 7/12 ✓
84	D American Golden Plover	7/15/78	4	2 eggs pipped 7/25 13:25 ✓ 2 chicks seen nest 1 just hatched

Aug. 7.

APPENDIX 9

Wetland classification according to Bergman 1977.

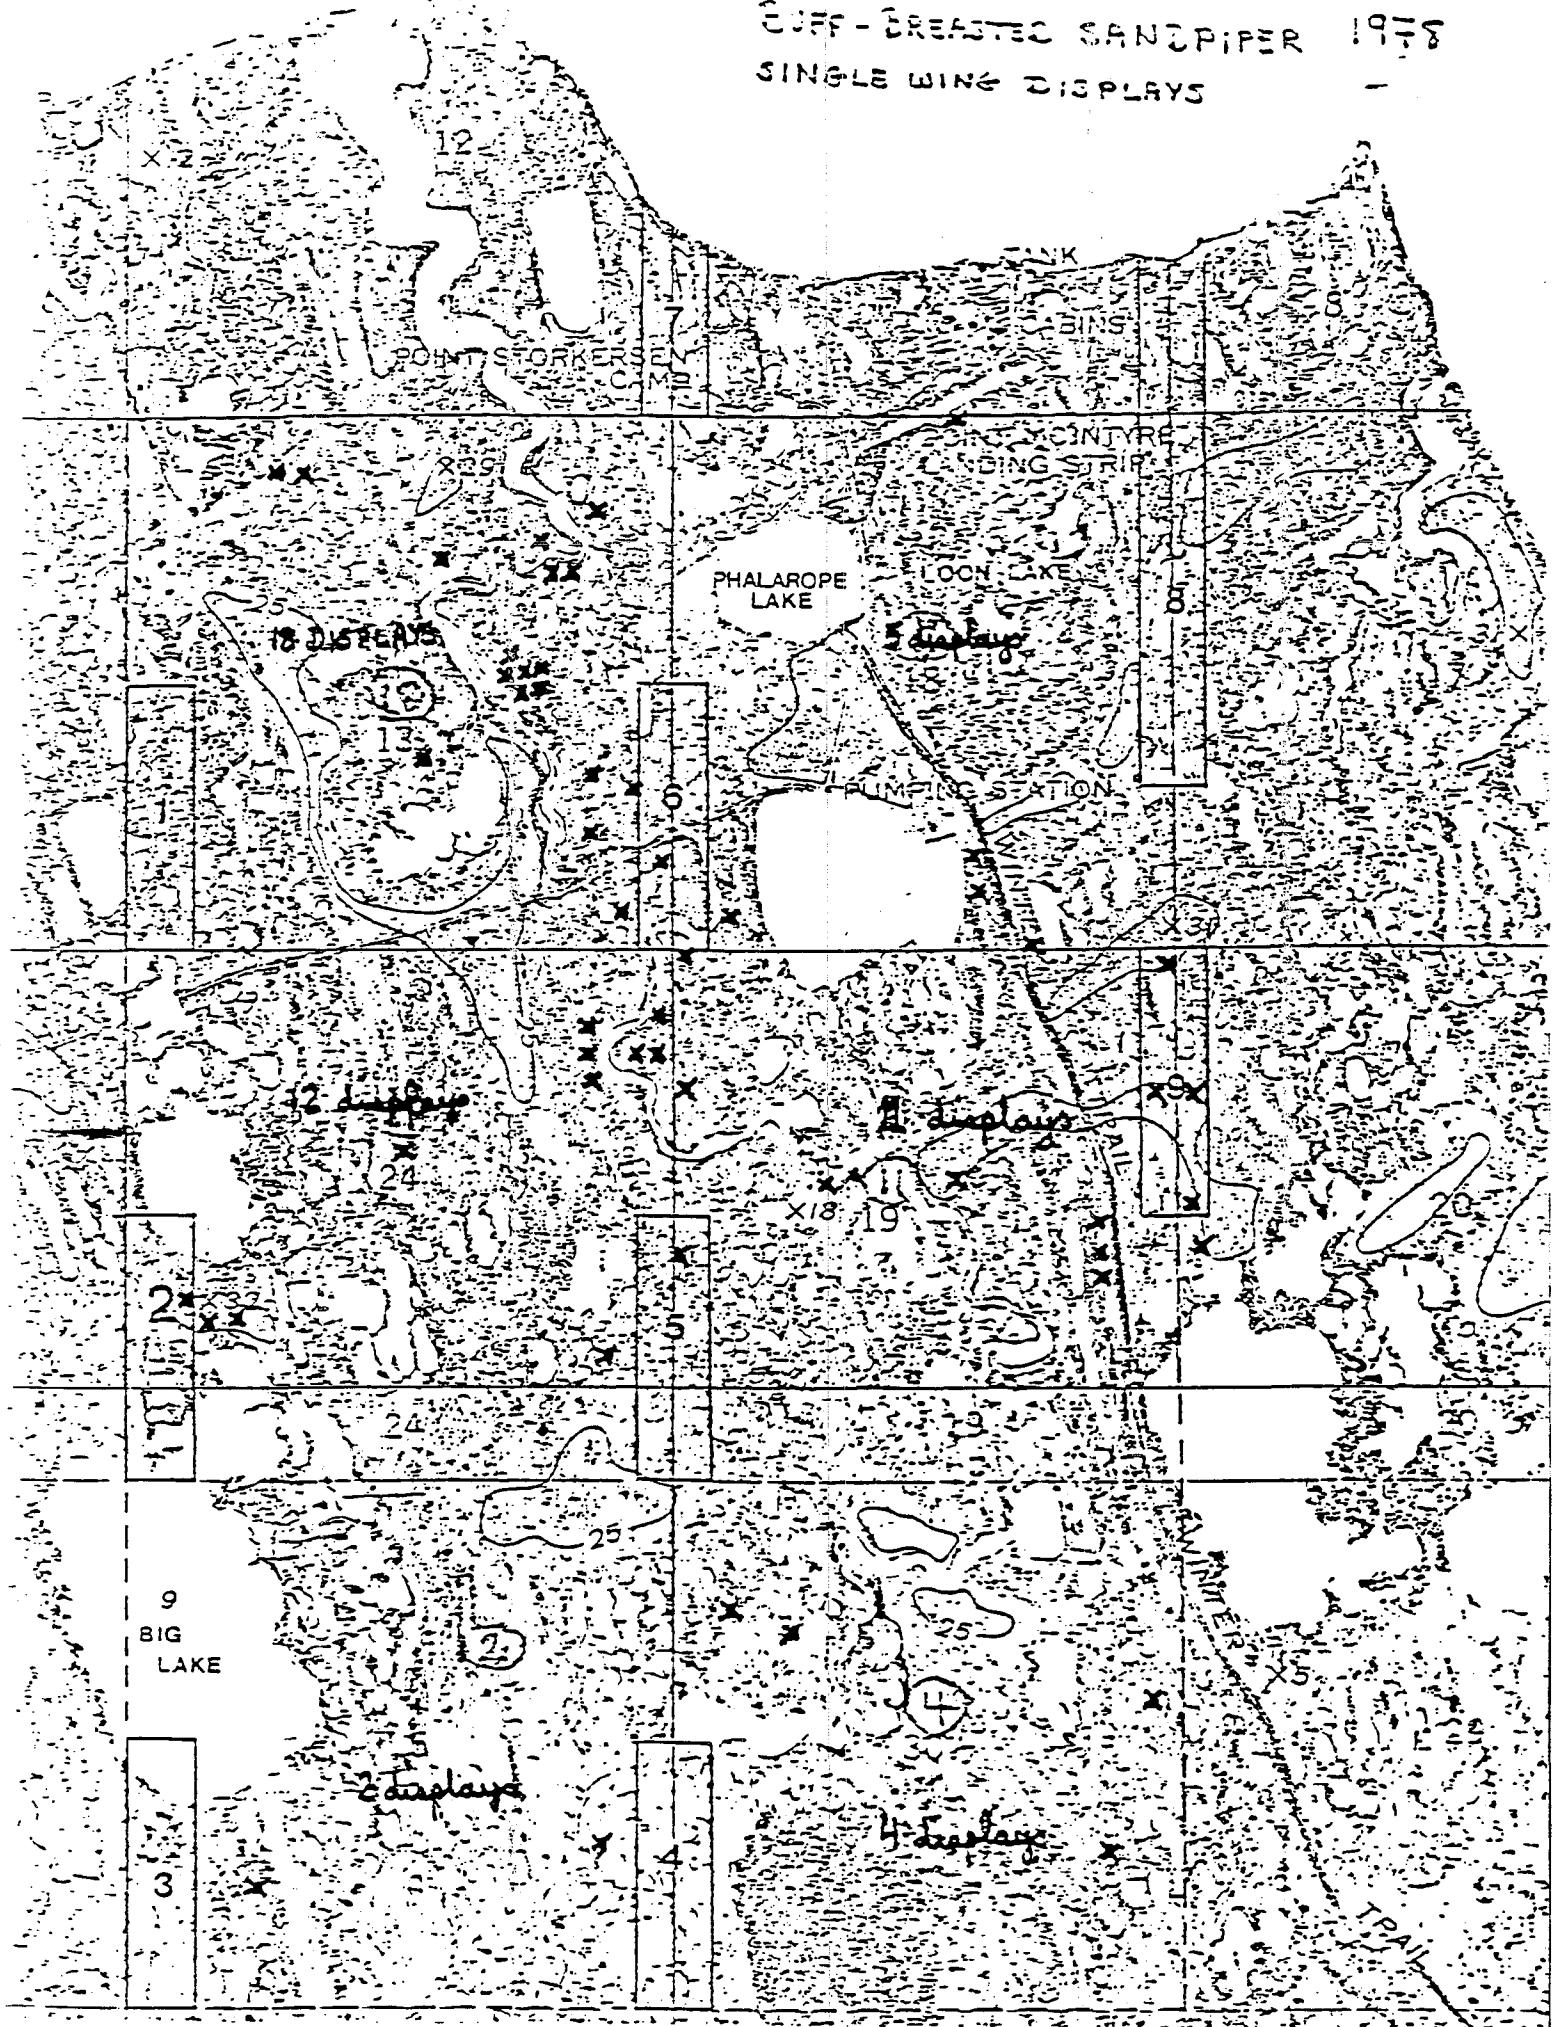

Wetland designation	Dominant emergents		Conductivity	Common size
	Shore zone	Central zone		
Flooded Tundra (Class I)	<i>Eriophorum angustifolium</i> or <i>Carex aquatilis</i>	<i>E. angustifolium</i> or <i>C. aquatilis</i>	Fresh or slightly brackish	Pond
Shallow-Carex (Class II)	<i>C. aquatilis</i>	Semi open to open	Fresh or slightly brackish	Pond
Shallow-Arctophila (Class III)	<i>C. aquatilis</i> or <i>Arctophila fulva</i>	<i>A. fulva</i>	Fresh or slightly brackish	Pond
Deep-Arctophila (Class IV)	<i>A. fulva</i>	Open	Fresh or slightly brackish	Pond or lake
Deep-open (Class V)	Open	Open	Fresh or slightly brackish	Lake
Basin-complex (Class VI)	Basin interspersed with <i>C. aquatilis</i> , <i>A. fulva</i> , and open water		Fresh or slightly brackish	Lake
Beaded Streams (Class VII)	<i>C. aquatilis</i> , <i>A. fulva</i> , or Open	Open or <i>A. fulva</i>	Fresh or slightly brackish	Pond= Bead
Coastal Wetlands (Class VIII)	<i>Puccinellia phryganoides</i> , <i>C. subsquarrosa</i> , or Open	Open	Brackish or subsaline	Pond or lagoon

NOTED SANDPIPER.

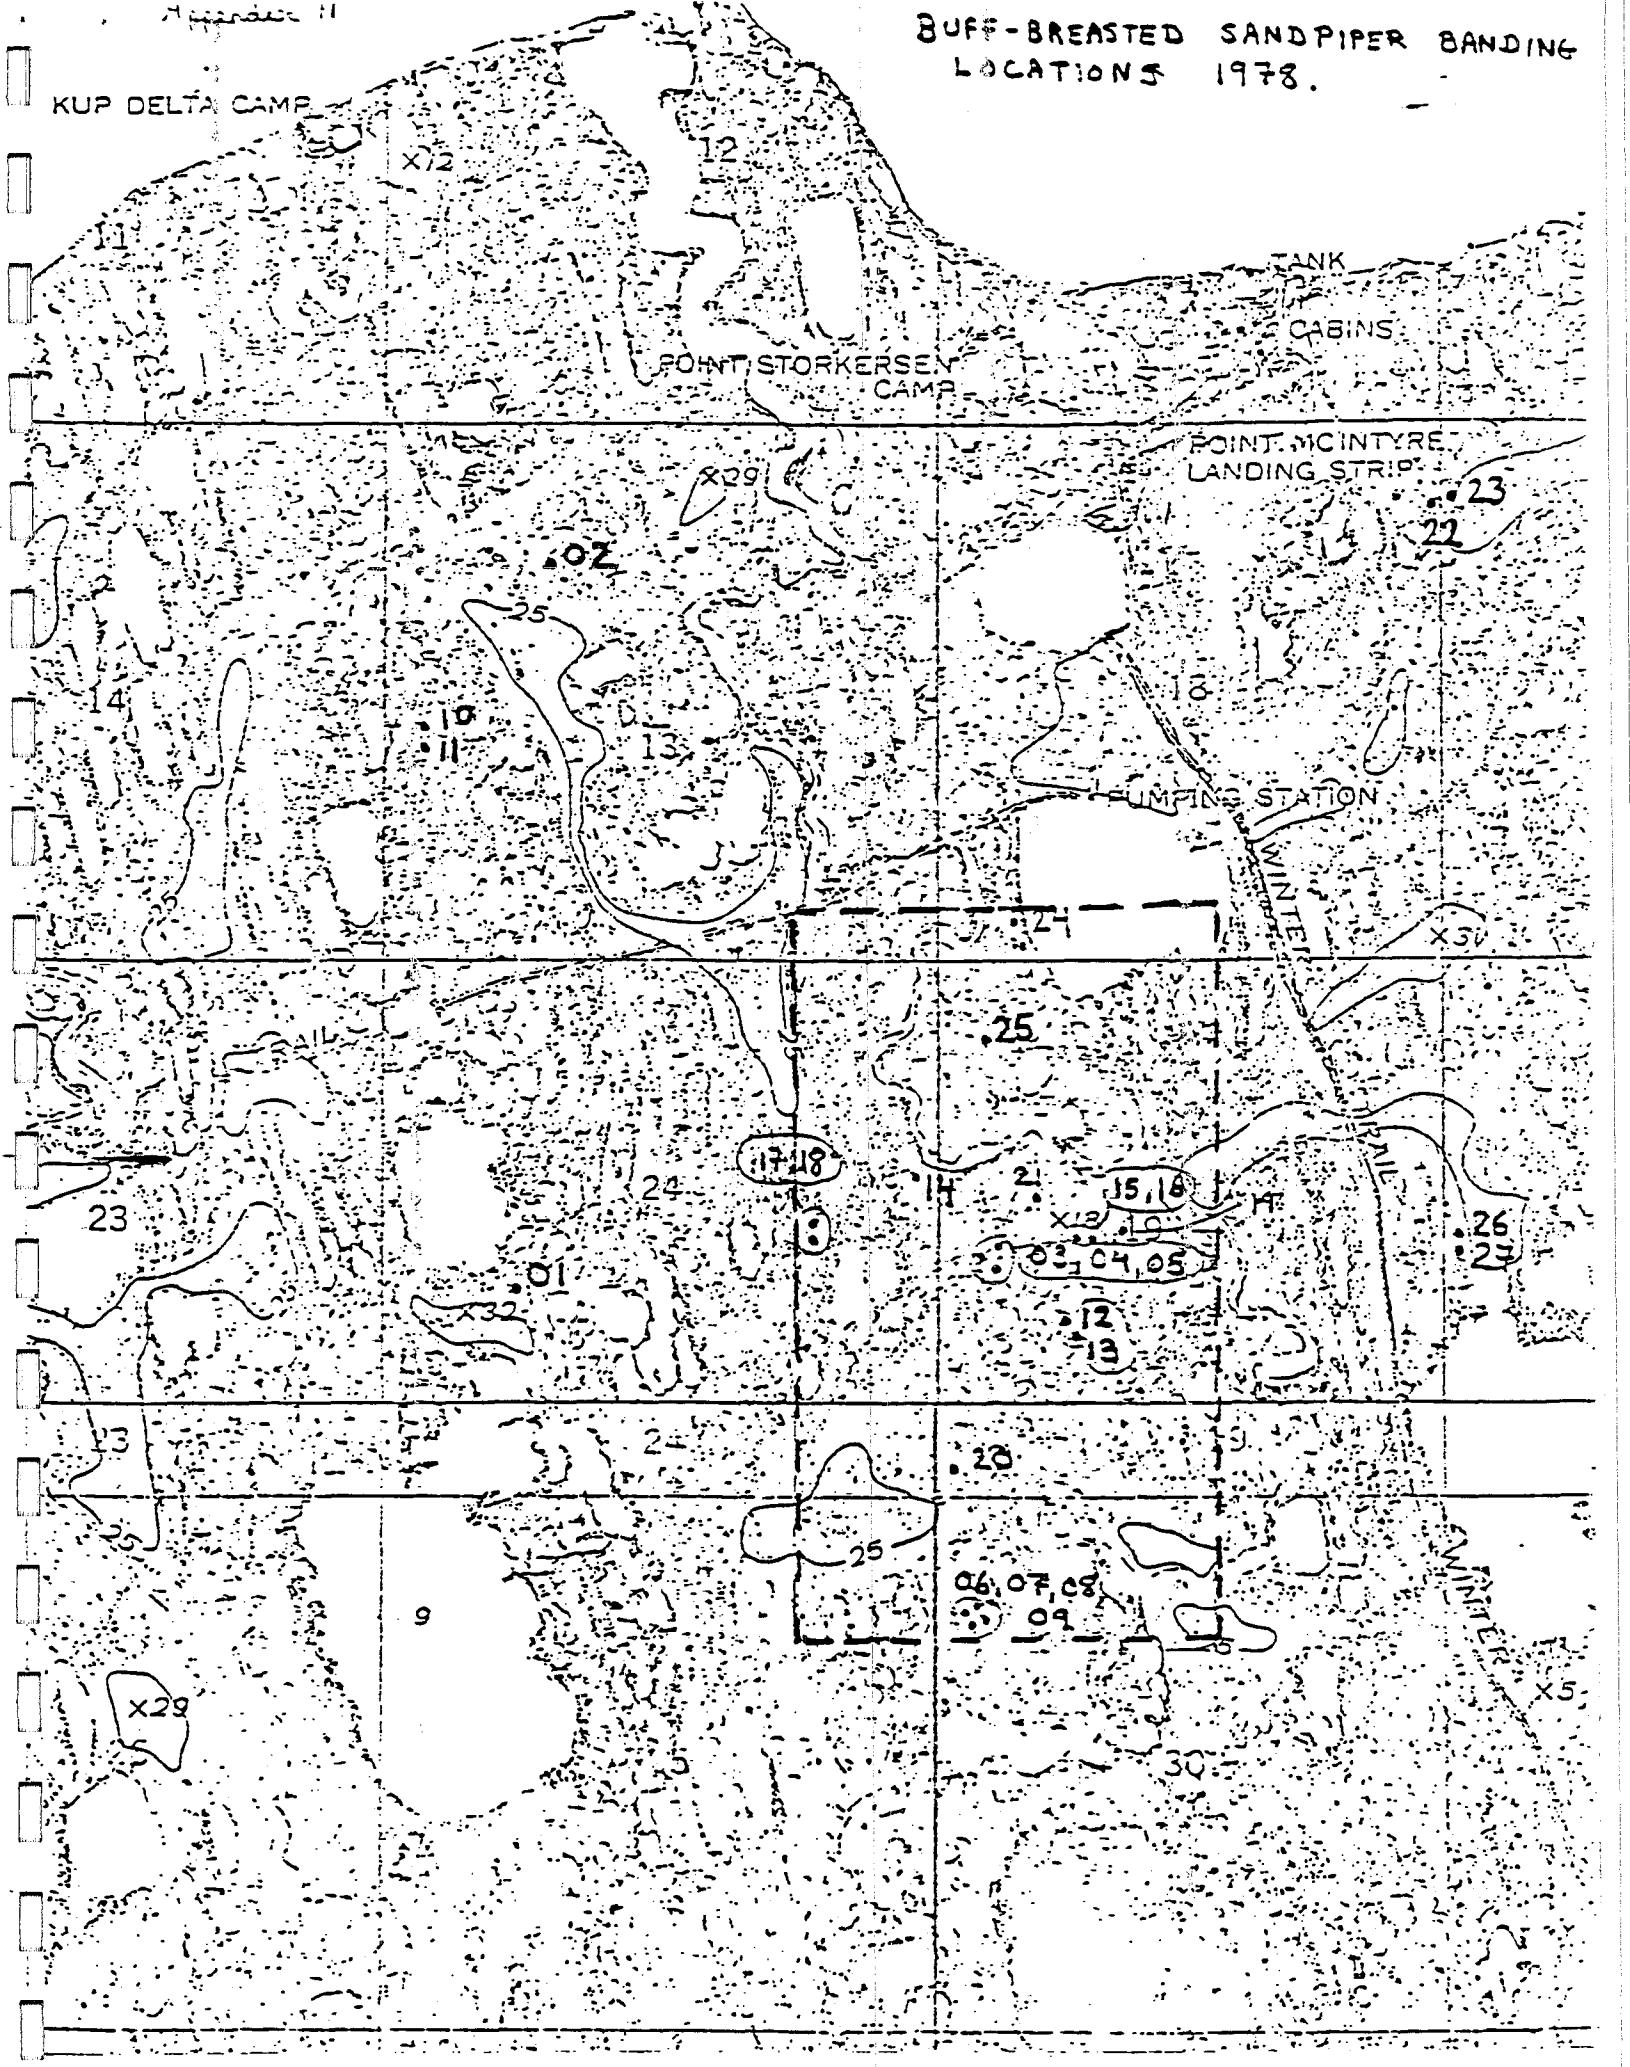

MARYS 1978

CUFF - BREASTED SANDPIPER 1978
SINGLE WING DISPLAYS

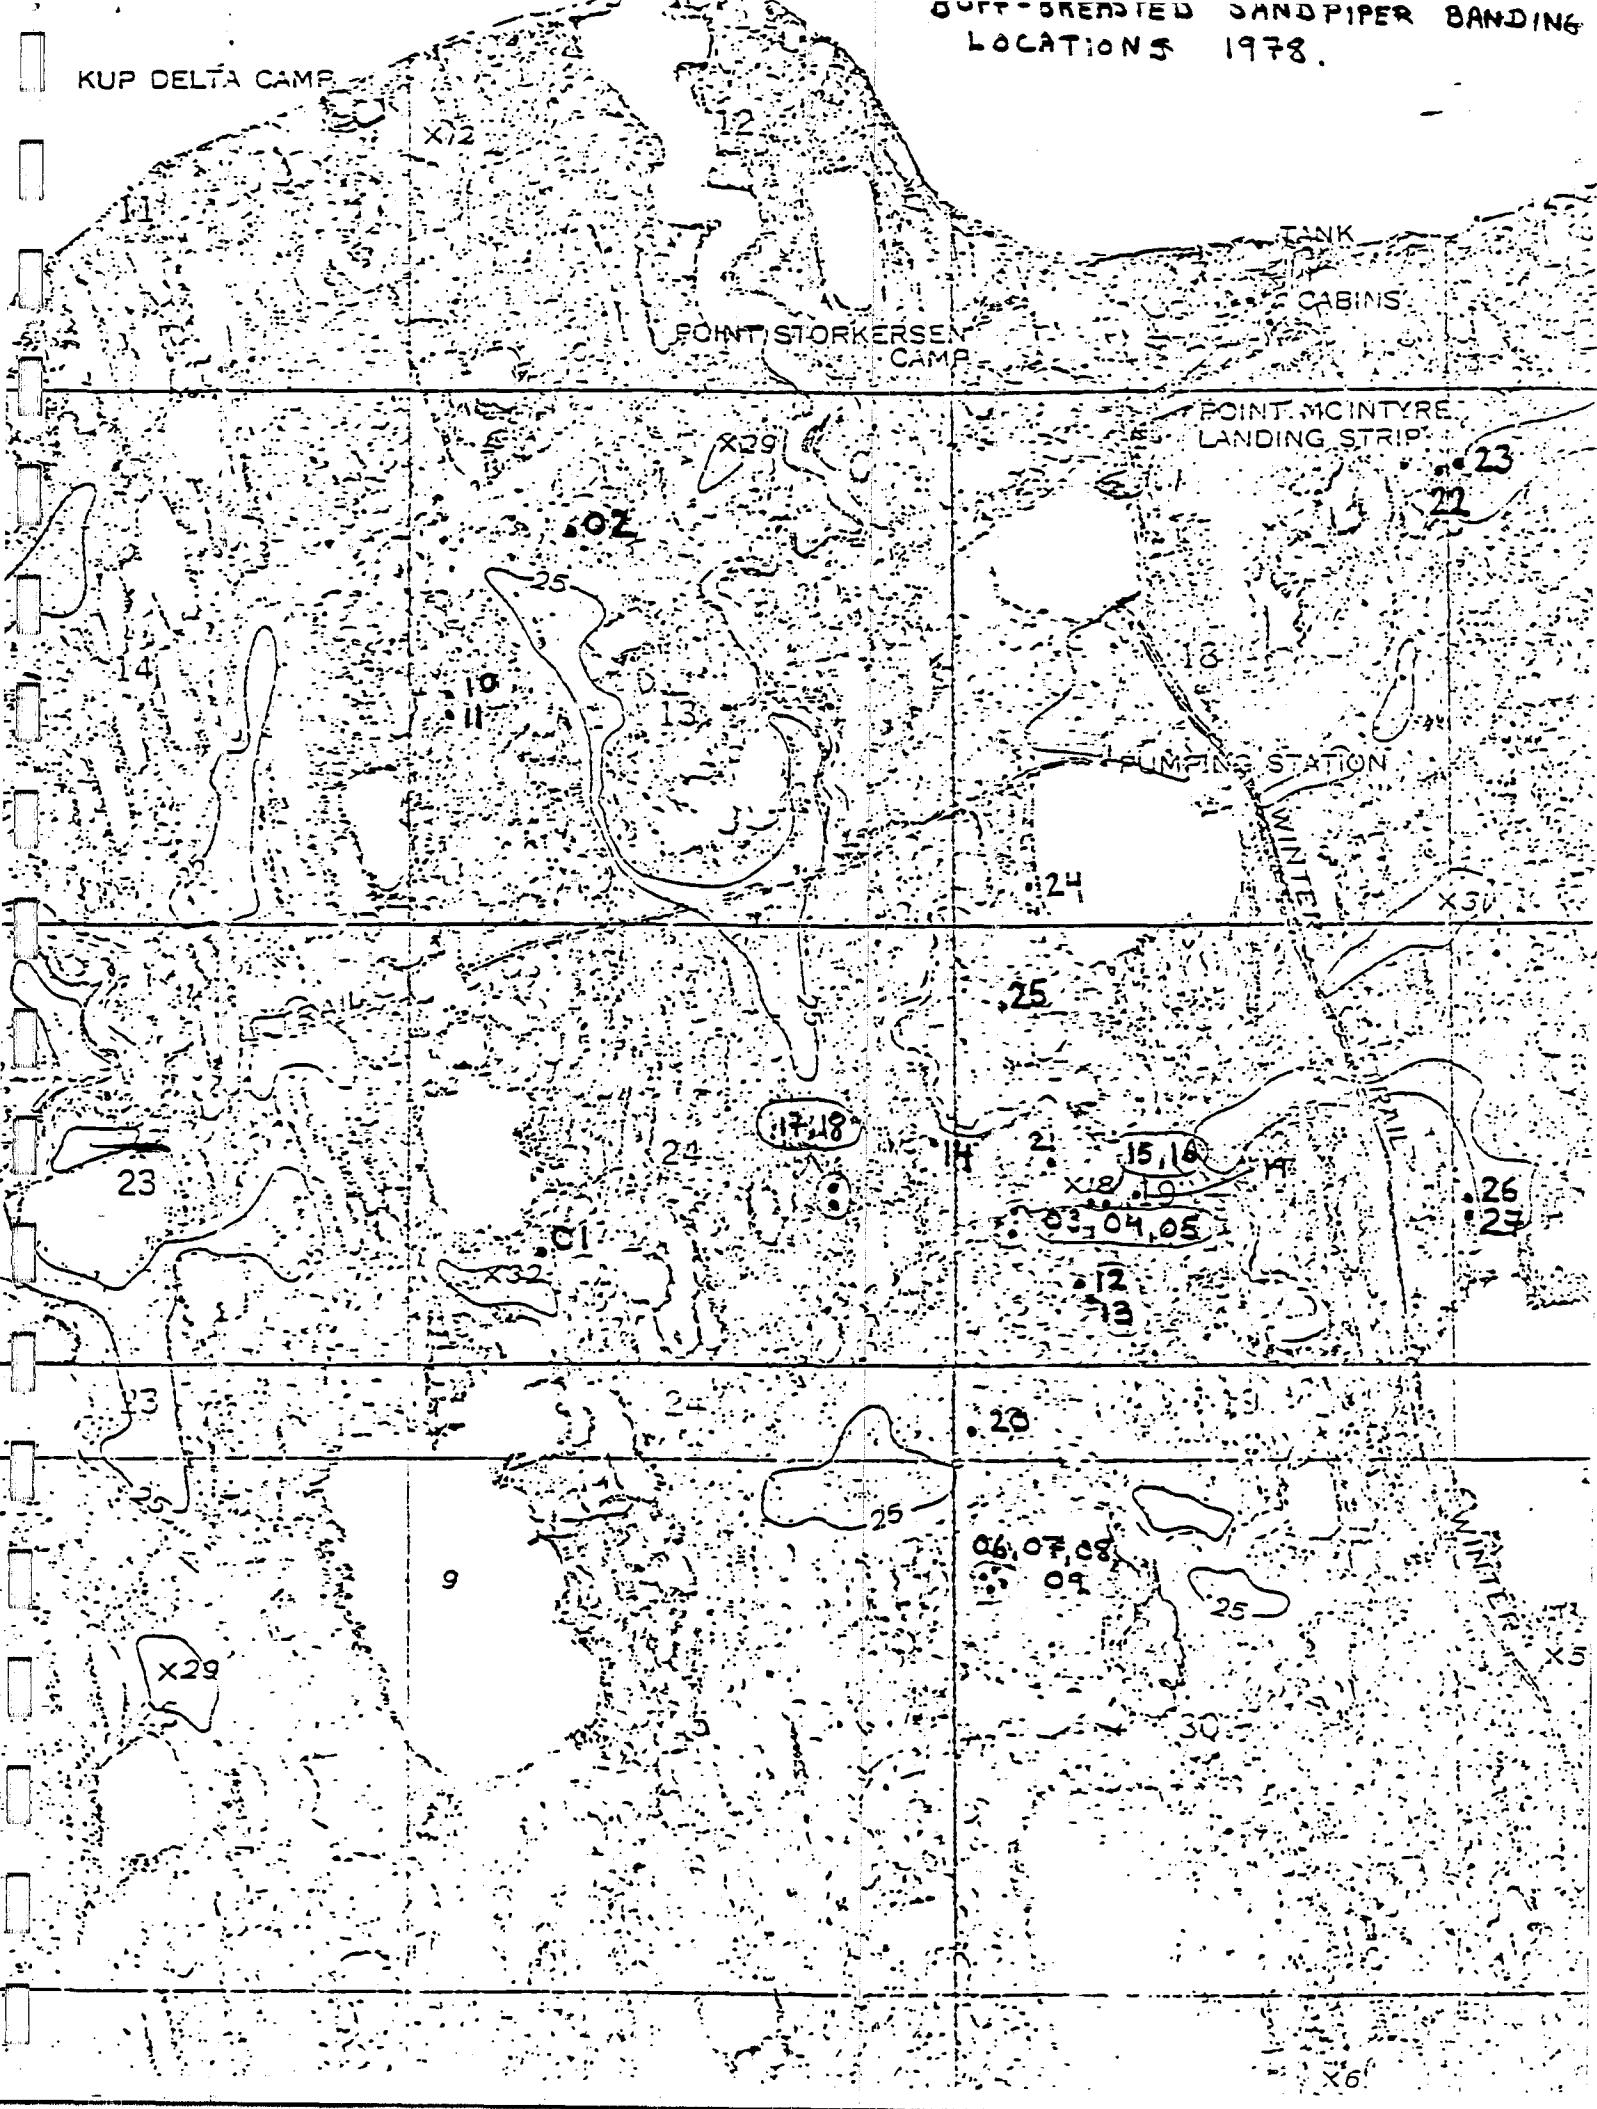

Appendix II
BUFF-BREASTED SANDPIPER BANDING LOCATIONS 1978.

			WEIGHT	SIZE	REDS	REMARKS
01.	Local 7/20	Right SIDE Left METAL	14	13	24	With headlight the bird seems very small but seemed fine. Walked as O.K.
02	Local 7/20	Right METAL left RED	32 7/24 45	15 15	29 inside 32 outside	On recapture bird seemed healthy. Same brood as #10, 11
03	Local 7/21	LEFT { { 2-3 above METAL below	34	15	27 inside	
04	local 7/21	RIGHT { { RED above METAL below	38	16		
05	local 7/21	LEFT { { RED above METAL below	43*	15		Scale loose weight may be inaccurate ~4 gms over at least
06	local 7/21	RIGHT { { BLUE above METAL below		14	31	Same brood as 07, 08, 09
07	local 7/21	Right METAL left Blue	46*	15	31	Scale loose weight may be inaccurate ~4 gms over at least Same brood as 08, 09, 10
08	local 7/21	Right RED left METAL	46*	15	31	Scale loose weight may be inaccurate ~4 gms over at least Same brood as 08, 09, 10
09	local 7/21	LEFT { { METAL above RED below	32	14	29	Same brood as 08, 09, 10
10	local 7/24	LEFT { { METAL above BLUE below	45	15	28 inside 30 outside	Same brood as 02, 11
11	local 7/24	RIGHT { { METAL above BLUE below	42	14	27 inside 29 total to toe	Same brood as 02, 10
12	Local 7/24	Right RED left { { BLUE above METAL below	42 45 (7/25)	14 14.5	27 inside 32 (side)	Same brood as 02, 10 Remeasured 7/25/78
13	Local 7/24	Right METAL left { { BLUE above RED below	46	15	28 inside	Resighted 7/25 Resighted flying on 7/30 in company with = 16
	local 7/24	Right { { BLUE above METAL below	43	14.5	27 inside	
	local 7/24	left RED				
	local 7/25	Right BLUE left { { RED above METAL below	54	17	36 inside 31 outside	Same brood as 02, 10

**BUFF-BREASTED SANDPIPER BANDING
LOCATIONS 1978.**

KUP DELTA CAMP

DATE OF BAND	LOCAL	BAND	MARKS	WEIGHT	TARSUS LENGTH	REMARKS	CROWN LENGTH	
							14	15
7/25	local	Right { BLUE above RED below		49	13	32 mm 27 inside		
7/25		Left METAL						
7/26	local	Right { RED above METAL below		34	14	32 mm 27 inside	Same brood as #18	
7/26		Left Red						
8	local	Right RED		34	14	32 mm 27 inside	Same brood as #17	
7/25		Left { METAL above RED below						
7/28	local	Right BLUE		54	17.5	33 mm 31 inside	Wings 144 mm. from side to tip stretched. 3rd barely feathered; flew but hard-case. Picture taken before banding.	
7/28		Left { METAL above RED below						
7/30	local	Right BLUE		37	15	32 mm 27 inside		
7/30		Left { BLUE above METAL below						
8/1	local	Right BLUE		42	16.5	33 mm 31 inside	Wings 130 mm. Chick and parent were measured at same time. Another chick 30 mm. / 2 weeks old.	
8/1		Left { METAL above BLUE below						
8/2	local	LEFT METAL (no plastic bands)		25		31 mm 27 inside	Wings 125 mm. Same brood. = 23	
8/2	local	RIGHT METAL (no plastic bands)		26	14	33 mm 31 inside	Wings ~ 132 mm; tarsus 29 mm. Tip of wing bent over, broken off at 1/3 of #22 and #23 which will cause discrepancy	
8/5	local	Right METAL		28	14	32 mm 31 inside	Same brood. Bands were re-measured. #15 mm - new measurement - 29 mm	
8/5		Left { RED above BLUE below		33	15	33 mm 30 inside	May be from nest 8 Remeasured 8/10/78	
8/8	local	Right { METAL above BLUE below		32	14.5	32 mm 29 inside	Obvious discrepancy 8/13 = suspect this is same brood as band #24	
		Left RED						
8/16	local	Right RED		35	13	32 mm 27 inside	Bill-weight discrepancy is not all due to inaccuracy. Birds may be lighter due to cold weather + lack of food. Tarsus length harder to explain. #26 + #27 are	
		Left { RED Above METAL below						
8/16	local	Right RED		33	13	31 mm 28 inside	#26 + #27 are of same brood	
		Left { METAL above
