List of Subjects in 50 CFR Part 17

Endangered and threatened species, Fish, Marine mammals, Plants (agriculture).

Regulation Promulgation

Accordingly, part 17, subchapter B of chapter I, title 50 of the Code of Federal

Regulations, is amended as set forth below:

PART 17—AMENDED

1. The authority citation for part 17 continues to read as follows:

DATE: Effective date of this rule is October 30, 1989.
ADDRESS: The complete file for this rule is available for inspection by appointment during normal business hours at the Service's Regional Office of Endangered Species, Federal Building, Fort Snelling, Twin Cities, Minnesota 55111.

FOR FURTHER INFORMATION CONTACT:
James M. Engel, Endangered Species Coordinator at the above address (612/725-3276 or FTS 725-3276).

SUPPLEMENTARY INFORMATION:
Background
The prairie fringed orchids, Platanthera leucophaea and P. praeclara are closely related members of the orchid family and are referred to as a species pair (Sheviak and Bowles 1986). Prior to description of P. praeclara the two species were considered as P. leucophaea, with a total range including 21 states and two provinces (Correll 1943, Luer 1975). Their joint distribution pattern extends from Oklahoma north to Manitoba, and east in a narrowing peninsula through the Great Lakes states to Maine. Populations also range westward through Nebraska in groundwater maintained habitats. P. leucophaea occurs primarily east of the Mississippi River, while P. praeclara is restricted to west of the Mississippi (Sheviak and Bowles 1986). Both species require full sunlight and usually inhabit tall grass calcareous silt loam or sub irrigated sand prairies. In the east, P. leucophaea also occupies calcareous wetlands, including open portions of fens, sedge meadows, marshes, and bogs (Bowles 1983).

The prairie fringed orchids are perennial herbs which regenerate from a fusiform tuber rootstock. Their tubers are dormant during winter and thus are adapted to dormant season prairie fires; such fires and high precipitation levels appear to promote flowering (Sheviak 1974, Roosa and Eilers 1978, Bowles 1983, Currier 1984). Leaves and an inflorescence (if flower primordia were set the prior year) usually emerge in May, and flowering begins by late June to early July. These species are characterized by large white flowers (the largest in the genus) arranged in an inflorescence that may reach 12 decimeters (47 inches) high with up to 40 flowers. The flowers are fragrant after sunset and adapted to pollination by night flying hawkmoths which ingest a high volume nectar resource from long nectar spurs (Bowles 1983). Pollination is required for seed production, while seedling establishment depends upon development of mycorrhizae with a favorable soil inhabiting fungus (reviewed in Bowles 1983). Differences in flower structures and pollination mechanics serve to isolate the species from hybridization; these features can be used to identify living or preserved specimens (Sheviak and Bowles 1986). The western species has larger flowers adapted to placing pollinia (pollen masses) on the compound eyes of visiting pollinators. In contrast, the eastern species places pollinia on the proboscis of visiting moths.

Platanthera leucophaea has declined over 70 per cent from original county records and now has about 52 extant populations in seven states. Primarily due to the destruction of large grasslands east of the Mississippi River, extremely large or extensive populations of this orchid do not exist in the United States. In Canada, 12 populations are known from fens and prairies in 12 Ontario counties; one fen population is estimated at 2000 plants (Brownell 1984).
The plant is also known from New Brunswick, where it is considered rare (Hinds 1983). However, most of these populations are not representative of the once vast prairie habitat that supported most populations of this orchid.

*Platanthera leucophaea* is presumed extirpated from Oklahoma, where the type specimen was collected by Nuttall in 1839 near the confluence of the Kiamichi and Red Rivers; it may have occurred in similar floodplain habitat in adjacent Arkansas (Shevick and Bowles 1986). This orchid reached its western range limit in Nebraska, where one historic record is known (W. J. Bailey, Jr., Nebraska Game and Parks Commission, *in litt.* 1988). It has not been relocated in Missouri (Morgan 1980), but one small population with three plants remains in Iowa. In the eastern United States, this orchid has not been relocated in New York, Pennsylvania, New Jersey, and Indiana; isolated disjunct populations still occur in Maine and Virginia (Bowles 1983). The Maine population occurs on private land, which is on the State's register of critical areas, in portions of an extensive fen that is undergoing some invasion by woody vegetation. Flowering plants appear erratically at this site. The current population appears to be about 20 adult individuals (Barbara Vickery, The Nature Conservancy, *in litt.* 1988). The small Virginia population occurs in a sedge meadow subject to light grazing. However, this population has not been observed since 1903 when three flowering stems were counted (S. M. Carbaugh, Virginia Department of Agriculture, *in litt.* 1988).

The eastern prairie fringed orchid is known historically from 23 Michigan counties: 18 populations (about half are protected) now are extant from nine counties, where 1322 flowering stems were counted in 1984 (Chapman and Crispin 1985). Southern Michigan populations are small and occur in isolated bog habitats; while several larger populations of over 100 plants occur in lakeside prairies bordering Saginaw Bay. Three large Michigan populations, totalling about 900 plants, occur on degraded upland prairies bordering Lake Erie. These sites are State owned, but extensive management is needed to maintain the orchids as their communities go through successional changes. A population near Bay City disappeared after severe flooding in 1986, and has not been observed since (G. T. Higgs, James Clements Airport Advisory Committee, *in litt.* 1986). The Saginaw Bay region continues to harbor the most viable populations in the state (Chapman and Crispin 1985). Frederick W. Case, Jr. (1987) states that *P. leucophaea* is possibly the region's most endangered orchid because of the destruction of its moist prairie habitat.

*Platanthera leucophaea* originally occurred in 11 Ohio counties and is now presumed extirpated from at least six. McCance (Ohio Department of Conservation, *in litt.* 1987) reported only two extant populations in 1987. The larger, containing about 60 flowering plants in 1987, was down from 307 plants in 1982. The other population contained 46 flowering plants in 1984, but only six plants were found in 1987. Smith (The Nature Conservancy, *in litt.* 1988) reports this population has further declined to two plants. Two other populations are known from sites frequently inundated by Lake Erie. One of these was located in 1987 when 24 plants were counted. Smith (1981) also observed this population in 1988 and counted 14 plants. The other site has not been relocated (C. R. Moseley, Jr. Ohio Department of Natural Resources, *in litt.* 1986). In Wisconsin, this orchid originally was known from 22 sites in 17 counties in the southern and southeastern portions of the state (Alverson 1981). Fourteen of these are known to be extirpated (J. Dobberpuhl, Wisconsin Department of Natural Resources, *in litt.* 1988). Nine small populations now occur in eight counties. One large population of several hundred plants occurs in a protected Lake Michigan border sand prairie in Kewaunee County. Illinois probably contained the largest and most extensive pre-settlement populations of the eastern prairie fringed orchid and also sustained the most drastic population decline of any state. Originally it was known from tall-grass prairies in 33 counties across the northern two thirds of the State, an area now almost totally converted to agriculture (Bowles and Kurz 1981). Eighteen populations remain in eight counties concentrated in the Chicago region; two additional populations occur in cemetery prairies in eastern and western Illinois counties. Only two populations consist of over 100 plants; both are in a Lake Michigan border county. Most populations are offered some form of protection, and only eight occur on private unprotected land.

*Platanthera praeclara* has experienced over a 60 percent decline according to county records, with about 37 populations remaining in seven states (Bowles and Duxbury 1986). Apparently, it has been extirpated from South Dakota where it was originally known from two counties. Populations in the southern part of this orchid's range seldom are observed. The two Oklahoma populations occur in privately owned hay meadows and were only observed during their original discovery (Magnath and Taylor 1978). This orchid was widespread in eastern Kansas, where it was originally known from 14 counties. Now, populations are reduced to eight counties where it has been noted to occur in seven privately owned hay meadows and one protected area on the University of Kansas research area (R. E. Brooks, U. of Kansas, *in litt.* 1987). Two small populations currently are known to occur in northwest Missouri. One population of five plants occurs on a private tract, while a second, of about 25 plants, is in a hay meadow recently acquired by the state.

Populations in the northern and central portions of the western prairie fringed orchid's range are larger and more extensive, but still reduced in size and range. This orchid probably was most widespread in the deep loess soils of Iowa, where a total of about 600 plants currently exist. Now, 13 populations are known from 11 Iowa counties (D. Howell, Iowa Department of Natural Resources, pers. comm. 1987). Most populations are small, with the largest consisting of about 275 plants. Six of the Iowa populations are in public or private conservation ownership and are managed by burning or mowing.

*Platanthera praeclara* originally was widespread in eastern Nebraska (Bowles and Duxbury 1986). A questionable historic record from 1842 attributed to Wyoming is now considered to be from Western Nebraska (H. Marriott, The Nature Conservancy, *in litt.* 1987). Five populations are known from four counties. Two populations are small (less than 20 plants each) and disjunct in western Nebraska; one occurs on a railroad right-of-way, while the other is on Federal land (Valentine National Wildlife Refuge) administered by the U.S. Fish and Wildlife Service. The federally owned tract is undergoing brush invasion. Three other sites in eastern Nebraska are on private or public land managed for conservation. Four of the five sites in Nebraska receive some type of protection and management. The largest population consists of about 150 plants. Five other *Platanthera praeclara* sites in Nebraska are assumed extirpated as their status is unknown.

One large scattered population occurs in North Dakota with approximately 2000 plants (Bowles and Duxbury 1986). The North Dakota population represents the type locality for *Platanthera*
requirement of the 1978 Amendments to the Act. On December 15, 1980 (45 FR 82479), and September 27, 1985 (50 FR 39623), the Service published revised notices of review for native plants in the Federal Register. Platanthera leucophaea (including in part the then yet undescribed P. proeclara) initially was included in those notices as a category 1 species. Category 1 species are those for which biological information in the Service's possession warrants listing as endangered or threatened. Later, this orchid was dropped to category 2, indicating that further biological research and field study were needed to ascertain its status.

The Endangered Species Act Amendments of 1982 required that all petitions pending as of October 13, 1982, be treated as having been submitted on that date. The deadline for a finding on those species, including Platanthera leucophaea, was October 13, 1983. On October 13, 1983, and again in 1984, 1985, 1986, and 1987, the petition finding was that listing of Platanthera leucophaea (including in part the then yet to be described P. proeclara) was warranted pending finding of further biological information but precluded by other pending listing actions, in accordance with section 4(b)(3)(B)(iii) of the Act. Such a finding requires that the petition be recycled, pursuant to section 4(b)(3)(C)(i) of the Act. The October 11, 1986 (53 FR 39621) proposal to classify Platanthera leucophaea and P. proeclara as threatened constituted the final required finding.

Summary of Comments and Recommendations

In the October 11, 1988, proposed rule and associated notifications, all interested parties were requested to submit factual reports or information that might contribute to the development of a final rule. Appropriate State agencies, county governments, Federal agencies, scientific organizations, landowners, and other interested parties were contacted and requested to comment. Notices inviting public comment were published in the following newspapers: Chicago Tribune, Chicago, IL; Des Moines Register, Des Moines, IA; The Globe-Gazette, Mason City, IA; Sioux City Journal, Sioux City, IA; Waterloo Courier, Waterloo, IA; Lawrence Journal-World, Lawrence, KS; The Leavenworth Times, Leavenworth, KS; Ottawa Herald, Ottawa, KS; Topeka Capital Journal, Topeka, KS; Bangor Daily News, Bangor, ME; The Bay City Times, Bay City, MI; Detroit Free Press, Detroit, MI; Three Rivers Commercial News, Three Rivers, MI; Austin Daily Herald, Austin, MN; Crookston Daily News, Crookston, MN; Rock County Stat-Herald, Luverne, MN; St. Joseph News-Press/Gazette, St. Joseph, MO; The Grand Island Independent, Grand Island, NE; The Lincoln Star and Lincoln Journal, Lincoln, NE; Valentine Newspaper, Valentine, NE; The Forum, Fargo, ND; The Ransom County Gazette, Lisbon, ND; Daily News, Wahpeton, ND; Tulsa Tribune, Tulsa, OK; Daily News Leader, Staunton, VA; Wisconsin State Journal, Madison, WI; The Janeville Gazette, Janeville, WI; The Milwaukee Journal, Milwaukee, WI; Oshkosh Northwestern, Oshkosh, WI between October 25, and November 3; and in the Sioux Falls Argus-Leader, Sioux Falls, SD, on November 22, 1988. Twenty-four comments were received, none of which opposed the rule. A summary of substantive comments is presented below.

Comments were submitted by two Federal agencies, twelve State agencies, three conservation organizations, and seven individuals. Fourteen responses supported listing while the remainder did not express a position. The U.S. Forest Service commented that the area in North Dakota, within the Sheyenne Ranger District (Sheyenne National Grassland), containing an extensive population of Platanthera praecvora (Western Prairie fringed Orchid) has been grazed for about 100 years, and the continued existence of the species, and the possibility it may be increasing, indicates to them that there may not be a need to list the species. However, the Forest Service acknowledges that plants must be listed rangewide, and because the species is declining elsewhere within its range, does not oppose the listing. The Forest Service points out that while overgrazing may be contributing to the decline of the species, there does not appear to be strong evidence that grazing by itself is as detrimental to the species as cropland conversion. The Forest Service has recognized the need to integrate rare species management into management activities on the Sheyenne Ranger District and has developed guidelines to protect the plant during haying and pesticide application. The Forest Service looks forward to a cooperative recovery effort and is initiating an Interim Management Plan specifically for the enhancement of this species, until such time as research has provided the answers for further management. The Soil Conservation Service office in North Dakota commented that a litter buildup may suppress P. proeclara, and rotational grazing may be beneficial.
The Sheyenne Valley Grazing Association commented that the Service is proposing to list *Platanthera praeclara* without knowing all the facts about the species, what is ideal habitat, how many plants there are, and if anything other than cropping is harmful to the species. In addition, the Grazing Association expressed concerns about the methods of listing plants, and if plants could be listed by population, the more healthy populations like the one on the Sheyenne National Grasslands would be unaffected. The Association does not oppose the listing, but believes even with listing we will not have all the answers. They want to be kept informed of the situation. The Service has completed range wide status surveys for *Platanthera praeclara* and *Platanthera leucophaea*. As a result of these surveys, and other biological documentation, the Service believes listing is appropriate. There might be instances where some populations of the plant may be in better condition than others, but range wide, both species have declined significantly and will continue to face threats of habitat destruction and alteration. By placing these species under the protection of the Act, the Service, and other cooperating Federal and State agencies will be able to complete recovery plans, initiate and complete research, and complete other management actions that will provide information to enhance both species’ survival.

The remaining comments, from State agencies, private conservation organizations, and individuals provided new species status information, advice of additional state protection, or lack thereof, mentioned the existence of localized threats to the species, and offered editorial comments concerning the rule. These comments have been incorporated into this final rule as deemed appropriate. A letter from a private conservation group supporting the listing was signed by 28 members of the organization.

Summary of Factors Affecting the Species

After a thorough review and consideration of all information available, the Service has determined that *Platanthera leucophaea* (Nutt.) Lindl. and *Platanthera praeclara* Sheviak and Bowles should be classified as threatened species. Procedures found at section 4(a)(1) of the Act and regulation 50 CFR part 424 promulgated to implement the listing provisions of the Act were followed. A species may be determined to be endangered or threatened due to one or more of the five factors described in section 4(a)(1). These factors and their application to *Platanthera leucophaea* (Nutt.) Lindl. and *Platanthera praeclara*

Sheviak and Bowles are as follows:

**A. The Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range**

The prairie fringed orchids have declined significantly throughout their ranges due to conversion of most of their habitats to cropland, overgrazing, intensive hay mowing, drainage, and for fire protection; these and related threats continue. Many of the largest *Platanthera leucophaea* populations occur in habitats supporting successful vegetation. Without management these populations may decline in response to changing vegetation patterns. Many other populations are small and occur on small isolated prairie remnants, where seed set and reproduction is limited by dependence on chance visitation from pollinators. Over 35 percent of the known populations of *Platanthera praeclara* occur in hay meadows; these plants seldom are seen, and populations apparently are small. Hay mowing annually removes seed capsules and plant biomass before natural seed dispersal can occur. This prevents recruitment of seedlings into populations and probably weakens adult plants, resulting in gradual population decline through attrition (Bowles 1983, Bowles and Duxbury 1986). Changing land use also threatens hay meadow populations. At least four Kansas hay meadows known to support *Platanthera praeclara* populations have been converted to cultivated cropland since their discovery in the 1970’s, while one Oklahoma hay meadow now is threatened with subdivision (Bowles and Duxbury 1988). The use of herbicides, especially on highway and railroad rights-of-way, continues to threaten these species in a number of instances (P.E. DeHond, Maine Planning Office, in litt. 1988, and L.G. Hiller, Ft. Ranson, ND, in litt. 1988).

**B. Overutilization for Commercial, Recreational, Scientific, or Educational Purposes**

Native terrestrial orchids rarely are grown from seed; adult plants are often sought for scientific and commercial purposes, or for private gardens. Smaller populations of the prairie fringed orchid would be adversely affected by collecting. Because of higher human population densities in the east, the eastern prairie fringed orchid is subject to greater scientific and commercial pressures; at least one Michigan population was affected by removal of plants. However, because of the recent description of *Platanthera praeclara* (western prairie fringed orchid) and its usually small populations, overcollecting may also become a serious problem for this species. At least one instance of removal of a western prairie fringed orchid plant for commercial purposes has taken place in Minnesota.

**C. Disease or Predation**

No diseases are known to be adversely affecting either prairie fringed orchid species. All inflorescences were removed from one Minnesota population of *Platanthera praeclara* by an unknown herbivore, but the long term impact remains unknown. Conehead grasshoppers (Orthoptera: Neocococephalus) occasionally are observed eating the flowers or fruits of these orchids. However, the major predator is man through use of this orchid’s community for pasture or hay. Long term overgrazing or haying apparently leads to population decline because plants either are harvested or are not allowed to complete their life cycles.

**D. The Inadequacy of Existing Regulatory Mechanisms**

The prairie fringed orchids are formally or officially listed as endangered, threatened, or rare in ten states (IA, IL, ME, MI, MN, MO, NE, ND, OH, WI) throughout their range. However, only a few states where these species are extant offer protection to listed plants beyond that afforded by their presence on public lands. State laws of Illinois, Iowa, Minnesota, Michigan, and Missouri prohibit the removal and sale of listed plants. Michigan prohibits transporting, buying, selling, possessing, or destroying in any manner. In Wisconsin, Ohio, and New York it is illegal to harvest endangered or threatened plants. Although *Platanthera leucophaea* and *P. praeclara* are offered various forms of recognition or protection under state laws, the Endangered Species Act offers possibilities for protection through section 6 by cooperation between States and the Service, and cooperation with other Federal agencies through section 7 (interagency cooperation) requirements. The plants are considered rare in Canada, but are not afforded any official designation or protection.

**E. Other Natural or Manmade Factors Affecting Its Continued Existence**

Pollination of the prairie fringed orchids is required for seed set, and is accomplished only by hawkmoths (Sphingidae). As a result, long-term
population survival requires maintenance of hawkmoths. Any threat to these insects (such as the use of insecticides) or their habitats and food plants, is a threat to survival of prairie fringed orchids.

The Service has carefully assessed the best scientific information available regarding the past, present, and future threats faced by these taxa, in determining to make this rule final. Based on this evaluation, the preferred action is to list Platanthera leucophaea and Platanthera praeclara as threatened species, because of the known loss of most of their populations and habitat, and continued threats to existing populations. For reasons detailed below, it is not considered prudent to propose designation of critical habitat.

Critical Habitat
Section 4(a)(3) of the Act requires, to the maximum extent prudent and determinable, that the Secretary designate critical habitat at the time the species is determined to be endangered or threatened. The designation of critical habitat is not considered to be prudent when such designation would not be of net benefit to the species involved (50 CFR 424.12). In the present case, the Service believes that designation of critical habitat would not be prudent because no benefit to the species can be identified that would outweigh the potential threat of vandalism or collection, which might be exacerbated by the publication of a detailed critical habitat description.

Available Conservation Measures
Conservation measures provided to species listed as endangered or threatened under the Endangered Species Act include recognition, recovery actions, requirements for Federal protection, and prohibitions against certain practices. Recognition through listing encourages and results in conservation actions by Federal, State, and private agencies, groups, and individuals. The Endangered Species Act provides for possible land acquisition and cooperation with the States. It also requires that recovery actions be carried out for all listed species. These recovery actions are initiated by the Service following listing. Some may be undertaken prior to listing, circumstances permitting. Potential habitat management actions that might benefit Platanthera leucophaea and P. praeclara include: evaluation and specific management actions on public lands to enhance orchid populations, land protection measures which will reduce frequent disturbance to both species’ habitat, and a program for landowners to educate them about the nature of their orchid populations and how they might alter management of their property to benefit these species. The protection required by Federal agencies and applicable prohibitions are discussed below.

Section 7(a) of the Act, as amended, requires Federal agencies to evaluate their actions with respect to any species that is proposed or listed as endangered or threatened and with respect to its critical habitat, if any is being designated. Regulations implementing this interagency cooperation provision of the Act are codified at 50 CFR part 402. Section 7(a)(2) requires Federal agencies to insure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its critical habitat. If a Federal action may affect a listed species or its critical habitat, the responsible federal agency must enter into formal consultation with the Service.

The Food Security Act of 1985 (Pub. L. 99-198) also provides at sections 1314 and 1316 opportunities for the Service and State conservation agencies to acquire restrictions on lands beneficial to endangered and threatened species on lands acquired by the Farmers Home Administration in the course of farm foreclosures. Upon notification by the Farmers Home Administration of pending foreclosures, the Service is continually reviewing possible areas where restrictive easements would benefit endangered and threatened species.

No Federal involvement is expected for Platanthera leucophaea since the species is not known to occur on Federal lands. Platanthera praeclara is known to occur on lands under the jurisdiction of the U.S. Fish and Wildlife Service on the Valentine National Wildlife Refuge, in Nebraska. Grazing management plans on the refuge should consider the effects livestock has on the species. A population monitoring program for P. praeclara should be initiated. A widely scattered population of P. praeclara is found on the Sheyenne National Grassland, Custer National Forest, Ransom and Richland counties, North Dakota. This population extends over several thousand acres managed by the U.S. Forest Service which in turn leases the area to the Sheyenne Valley Grazing Association for livestock production. The Forest Service and the Grazing Association are aware of P. praeclara. The species is found on 25 of the 58 allotments within the Sheyenne National Grassland. In order to meet the intent of the Act, the U.S. Forest Service.

Federal Register / Vol. 54, No. 187 / Thursday, September 28, 1989 / Rules and Regulations 39861
because these plants belong to the orchid family, species of which now are sought for cultivation.

On July 1, 1975. Platanthera leucophaea was included in Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), which is implemented through section 8A of the Act. The effect of this listing is that generally, both export and import permits are required before international shipment may occur. Such shipment is strictly regulated by CITES member nations to prevent it from being detrimental to the survival of the species, and generally, cannot be allowed if it is for primarily commercial purposes. If plants are certified as artificially propagated, however, international shipment requires only export documents under CITES, and commercial shipments may be allowed. Requests for copies of the regulations on plants and inquiries regarding them may be addressed to the Office of Management Authority, U.S. Fish and Wildlife Service, P.O. Box 3507, Arlington, VA 22203, (703)358-2093.

National Environmental Policy Act

The Fish and Wildlife Service has determined that Environmental Assessments, as defined under the authority of the National Environmental Policy Act of 1969, need not be prepared in connection with regulations adopted pursuant to section 4(a) of the Endangered Species Act of 1973, as amended. A notice outlining the Service's reasons for this determination was published in the Federal Register October 25, 1983 (48 FR 49243).

PART 17—[AMENDED]

Accordingly, part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations, is amended as set forth below:

1. The authority citation for part 17 continues to read as follows:

2. Amend § 17.12(h) by adding the following, in alphabetical order under the family Orchidaceae, to the List of Endangered and Threatened Plants:

§ 17.12 Endangered and threatened plants.
